If there is one machine more than another where

## Absolute Accuracy

is required, it is in the construction of an Experimental Lathe.

Accurate fitting, assembling, aligning of head and tailstock and carriage with lathe bed, is found without exception in the "Hendey."

Motor-driven. Besides regular equipment it has small tool cabinet for operators' fine tools—also gear closet for extra gears to cut special threads.

**Let us tell you more about it.**

# Some Applications of Air-operated Machine Tool Equipment

Staff Article

*The tendency to use specialized equipment when the output is sufficient to justify the expense is now thoroughly established amongst progressive manufacturers, and the resume of various applications of compressed air to increase production and save labor forming the accompanying article should serve a helpful purpose refreshing the minds of many readers.*

MANUFACTURING efficiency is almost entirely a question of maximum and accurate production on a speedy and economical basis, to achieve which it is essential that every facility be provided. This does not imply that the most modern equipment should be obtained for the specific purpose—although this is advisable where initial machinery is installed—but in cases where plants are already equipped with suitable tools it is very important that they be so equipped and utilized that their effectiveness is constantly maintained. While labor saving devices are not always a fundamental consideration in the manipulation of machine shop equipment, they are nevertheless a very important factor in the operation of a plant where considerable physical effort is required on the part of the workmen during the course of a day's work. Apart from the actual duties of a machine tool, production is governed by the ability of the operator to keep pace with the physical requirements of his work. In the making of munitions during the past three years, the outstanding feature has been the physical nature of much of the incidental work in connection with the manufacture of the shells this condition being especially pronounced during the incipient stages of the industry. Early methods of routing the shells for individual machine operations involved excessive handling of the shells in and out of the various machines.

### Early Neglect of Chucking

With the increasing demand for more shells plant executives were called upon to devise means to enhance their previous efforts in regard to production. The special or single purpose machine tool has without doubt been the chief factor in the solution of the stupendous problem of munition manufacture; and the remarkable success of this type of equipment was the primary incentive to the ingenuity of plant engineers and mechanics in devising special attachments for the accomplishment of a specific purpose. Equal in importance to the development of the single purpose tool has been the advancement of chucking, both externally and internally, for the various sizes of shells. In the early days of munition activity, the importance of chucking was not given the same consideration as other detail operations, but it was soon recognized that this feature was of the greatest importance. Those firms that took up the work at a later date were fortunate in that they were relieved to a considerable extent of the experimental work experienced by the pioneers of the industry.

### Progress of Air Devices

The adaptation of compressed air for the operation of chucking fixtures of every description has probably made greater progress than any other single detail in connection with munition manufacture. The uniform nature and quantity of the product practically eliminated the use of the ordinary independent or universal chuck, these being replaced by suitable collet chucks. At first these were usually operated by hand control, but this method was to a great extent superseded by pneumatic appliances; its

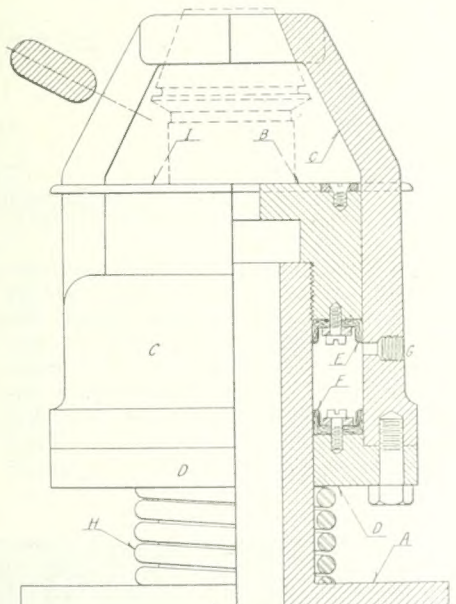

FIG. 1. AIR-OPERATED JIG FOR DRILLING AND REAMING SMALL HOLES IN DETONATING FUSES.

application for this purpose proved more rapid and reliable, and also relieved the workman of the tedious duty of operating the draw-rod by means of the hand wheel or heavy wrench at each insertion or removal of the shell. Where compressed air is not available the initial cost of installing an air compressor is, of course, a question that demands serious consideration.

In general, the expansive force of compressed air is used against a freely moving piston connected to a draw-rod for operating the gripping jaws of the collet chuck or expanding arbor. For lathe work the more common types of air control have the air cylinder secured to the rear of the spindle, the inlet being provided with gland connection to prevent the escape of air while the parts are in motion. This is an important detail on those machines where the work is revolved. When the pneumatic principle of chucking is adopted on machines where the tools are in motion, the necessity of one of these air connections is eliminated; this is the case on those fixtures used on drilling machines, jigs, etc.

### Rapidity and Accuracy

In the operation of jigs and fixtures rapidity of action is second only to the accuracy of the device in which the work is held. As in all other classes of machine shop work, the handling of the material and the time required to set the tools or attachments are the essential factors upon which efficiency is based; and it is therefore imperative that, apart from the actual machining of the piece, the period between operations—or the handling of the work—should be reduced to the lowest possible minimum. Where pieces are to be placed in jigs or fixtures for subsequent machining, it is very important that the clamping arrangement be of such a character that the pieces can be inserted and removed from position with minimum effort and loss of time. Various methods are adopted for holding work in fixtures during machining operations, the general practice being by the use of wing nuts or suitable cam clamps. While the effort required on the part of the operator is seldom such that actual fatigue results from work of this nature, it is often advisable to give due consideration to the conservation of the workman's energy even in those details that are invariably classed as insignificant.

The adaptation of compressed air to jig work is worthy of more attention from those who are called upon to perform work that requires rapid handling for economic production; particularly where large quantities are to be manufactured and the actual machining is light compared to the entire cycle of handling and tooling of the piece. The sketch shown in Fig. 1 illustrates a jig that has proven very satisfactory for holding detonating fuse bodies while certain of the drilling and reaming operations are being accomplished. The plant where this device is used employs quite a staff of female workers and it is characteristic of the management to adopt ways and means wherever possible to facilitate production without demanding excessive physical effort from those who are called upon to operate the equipment. The jig consists of a stand

A, that can be permanently fixed upon the drill table, or moved about as desired. To the upper end of the pillar of A is screwed the piece B that forms the piston of the device, which owing to the construction, is a stationary member, the cylinder or outer portion C moving vertically up and down with the action of the compressed air. The piece D forms the head of the cylinder, the U leathers E and F forming the necessary air-tight joints; G is the pipe connection for the air supply. A heavy coil spring

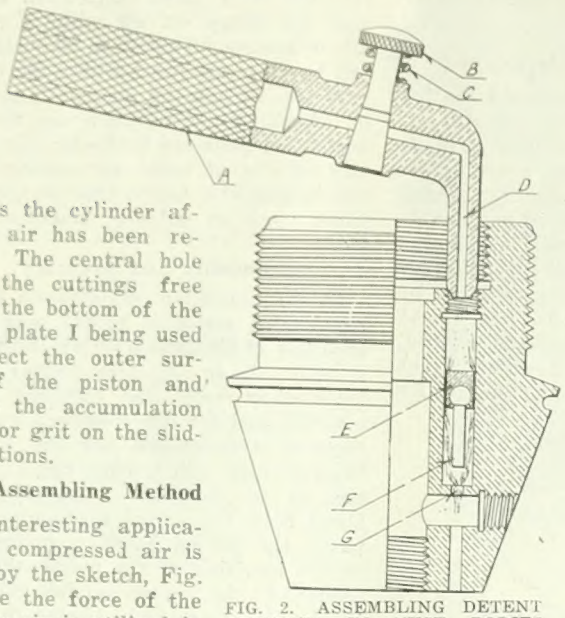

FIG. 2. ASSEMBLING DETENT SPINDLES IN FUSE BODIES WITH COMPRESSED AIR.

H raises the cylinder after the air has been released. The central hole allows the cuttings free exit to the bottom of the jig, the plate I being used to protect the outer surface of the piston and prevent the accumulation of dirt or grit on the sliding portions.

### Novel Assembling Method

An interesting application of compressed air is shown by the sketch, Fig. 2, where the force of the escaping air is utilized in the assembling of detonating fuses. Before adopting this method considerable difficulty was experienced in getting the detent spindle to enter the small hole; the air, however, solved the problem. After the detent has been dropped in place, the nozzle of the hose connection A, is placed in the detent hole as shown, so that when the button B is pressed down, a current of air is forced through the passage D and then through the larger hole in the fuse. As the air rushes on the pieces E and F are held in a central position by the vortex of rushing air, so that the point of the pin F is drawn into the small hole G without interference. An insignificant volume of air is sufficient for the desired purpose.

In the construction of the shrapnel shells it is necessary to machine the brass socket after the same has been firmly screwed to position, following the filling of the interior with bullets and resin. Owing to the fact that the copper band has been previously pressed on and turned, its larger diameter offers an inconvenience to the ordinary method of chucking. To overcome this, the chucking fixture shown in Fig. 3 was designed; in the general run of pneumatic chucks the stroke is comparatively short, but due to the special method adopted of placing the shell in position, the stroke of the device here shown was about 5 in., the control rod being in compression instead of in tension. After the sockets are screwed in and the tube soldered, the shells are placed in the chuck from the side and as the ram of the air piston is forced forward, the shell is held firmly in position while the brass socket is finish turned. The shell jig is secured to the driven plate of the lathe and has two rigid arms extending out to a circular portion that revolves in a separate steady head. The entire machining of the socket is performed by the movement of the handle at the right, the outer edge being finished when lever is pushed in one direction and the inner portion machined when lever is moved in the opposite direction.

### A Vertical Chuck

An interesting illustration of a pneumatic operated device is shown in Fig. 4. The entire fixture is of special design and worthy of particular attention; its purpose is to hold the shell firmly

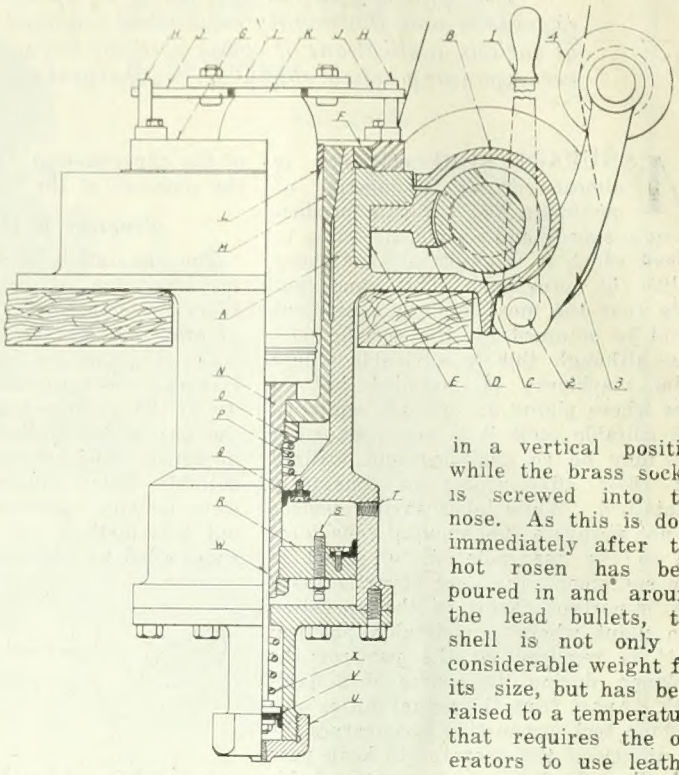

FIG. 4 SOCKET-SCREWING MACHINE WITH TWO-CYLINDER PNEUMATIC GEAR.

in a vertical position while the brass socket is screwed into the nose. As this is done immediately after the hot rosen has been poured in and around the lead bullets, the shell is not only of considerable weight for its size, but has been raised to a temperature that requires the operators to use leather gloves while they are being handled. For this reason it is very important that every facility be provided to perform the various operations in the shortest possible time. The body A, which is bolted firmly to the bench, is of special design, the upper portion constructed to contain the collet chuck and the revolving mechanism, while the lower portion contains the two cylinders, the larger one for the chuck control, and the smaller one at

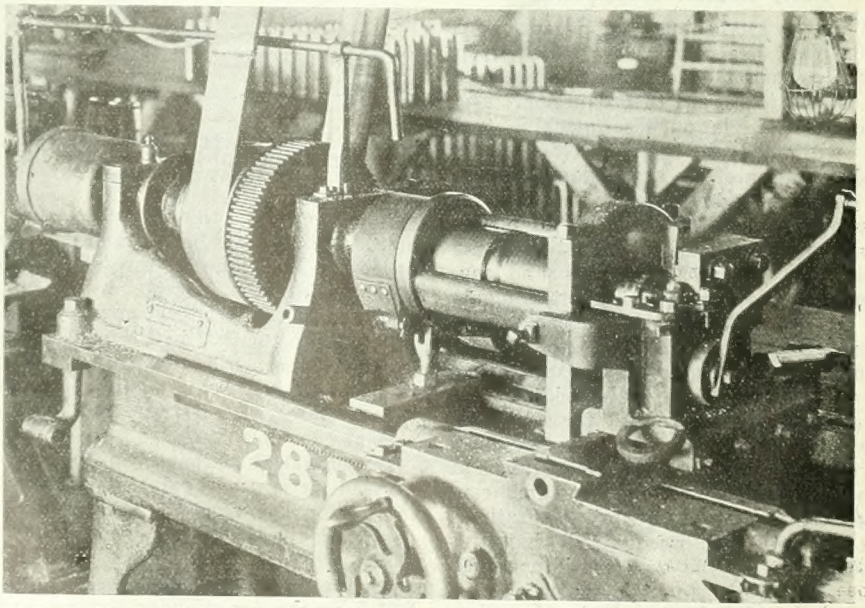

FIG. 3. AIR-OPERATED CHUCK FOR HOLDING SHRAPNEL SHELLS WHILE FINISHING BRASS SOCKETS.

the bottom for ejecting the shell after the socket has been screwed into position. To one side of the upper portion of the body an enclosed section B is provided to carry the worm shaft and worm C, the latter engaging with the worm gear D which is secured to the

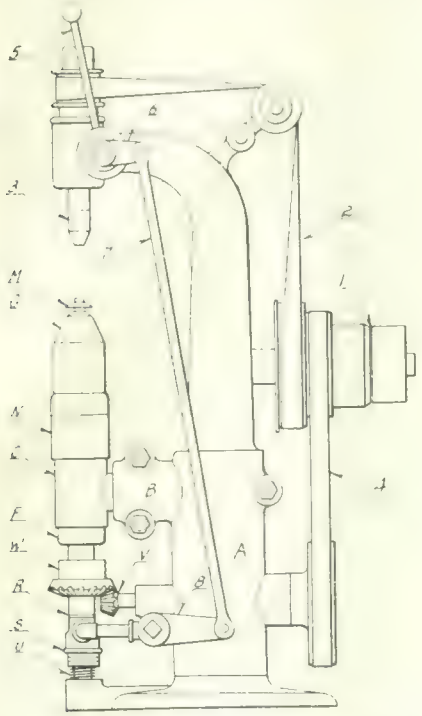

FIG. 5. DETAILS OF GRAZE PELLET DRILLING ATTACHMENT.

large ring E and held in position by retainer F. Fastened to the flange of the ring E is another steel ring G that carries the driving dogs H, of which there may be two or three as desired. To a small ring I is secured the levers J, the inner end of which are serrated to grip the brass socket when driving the same. As the copper band is of a larger diameter than the body of the shell, it is necessary to slip a thin split ring L over the shell before the same is dropped into the collet chuck M. To the lower portion of the collet is attached the draw rod N secured by the nut O, the spring P releasing the grip on the shell when the air pressure has been removed. Through the piston R is an adjustable bolt S for controlling the travel of the collet when releasing or tightening the chuck. The air inlet is shown at T. To facilitate the removal of the shell from its position in the chuck an additional cylinder is located below the larger one, so that when the chuck is released the piston V is forced upwards and the rod W that passes through the draw rod N, pushes the shell out of the chuck, so that it is easily grasped by the operator, the spring X lowering the rod when the air has been released.

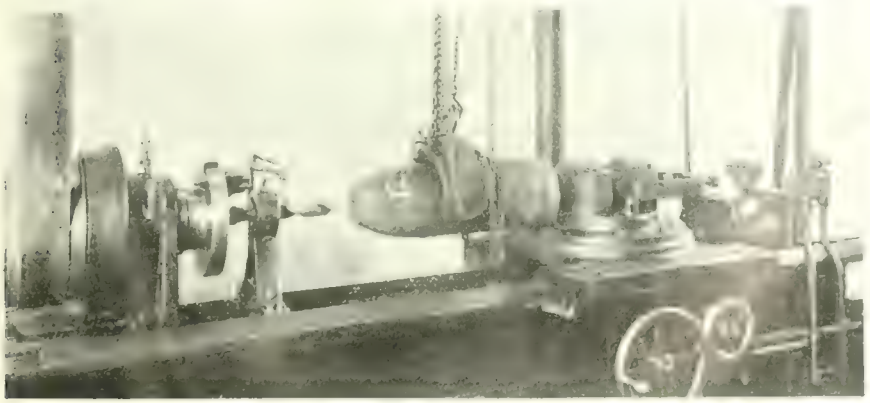

FIG. 7. DRILLING NOSE OF LARGE SHELL WITH BRASS [illegible] INLET IMPROVISED AS AIR FEED DEVICE.

### Insuring Concentricity of Drilling

In the manufacture of certain details in connection with the making of fuses, accuracy is an essential. In order to drill the small hole in the center of the pellet plug of the detonating fuse and assure of its being concentric with the outer portion the small but interesting drilling machine shown in Fig. 5 was designed and has given entire satisfaction. The machine is so constructed that the drill spindle is made to revolve at a speed of about 1,200 per min., while the lower portion that carries the work revolves at a speed of about 300 revolutions per min. in the opposite direction, so that the actual speed of the drill in relation to the work is practically 1,500 revolutions per min. This virtually insures a drilled hole central and concentric with the outer circumference. A notable feature in connection with the operation of this attachment is the joint control of the drilling and the chucking of the work with the one motion of the lever. After the pellet plug is placed loosely in the chuck the downward movement of the lever 5, which actuates the drill spindle 3, also operates the air valve on the lower end of the connecting rod 7, which is so adjusted that the initial movement of the sensitive lever opens the valve and allows air to enter the operating cylinder, the reverse motion of the lever raising the drill and releasing the chuck.

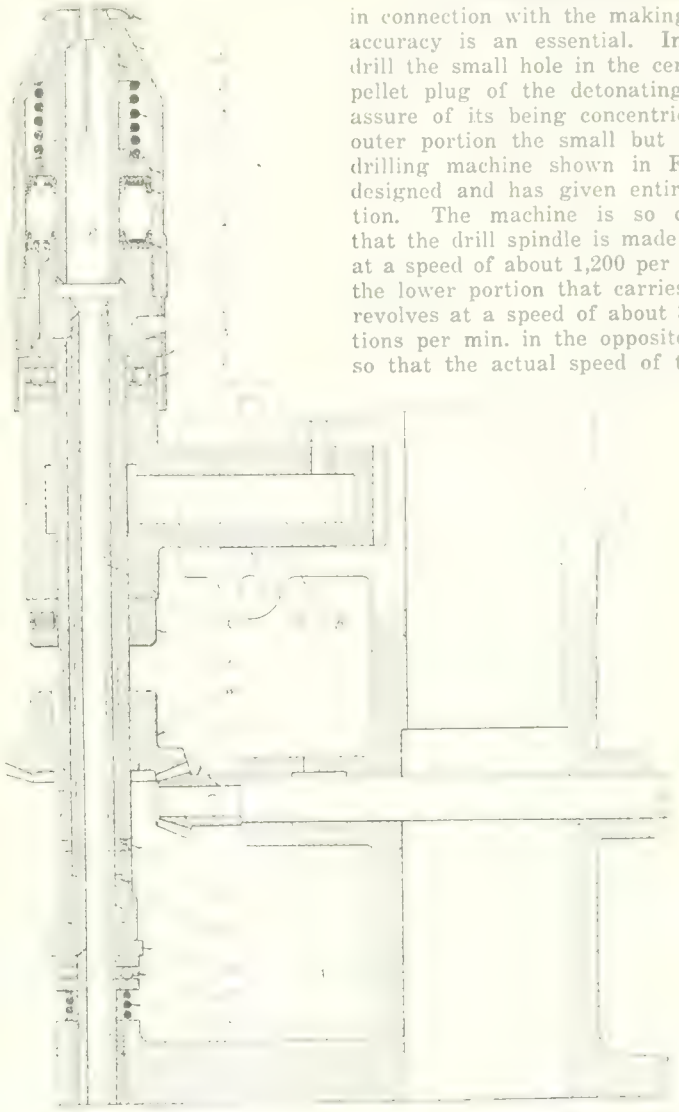

FIG. 6. SECTIONAL ELEVATION OF CHUCKING AND REVOLVING DEVICE IN FIG. 5.

A [illegible] arrangement and operating mechanism is shown in Fig. 6. The frame or stand A is bolted to the bench, the upper ex-

least possible friction, vertical motion justable collar F. The shell G of the chuck is threaded to the upper section outer cylinder and the smaller portion the air is released the collet is lowered by the reaction of the coil spring L. A small cup shaped piece of sheet steel is fastened to the top of the collet to prevent the dirt or cuttings from entering into and destroying the sliding portions. A similar cylindrical shield is attached to the side of the main spindle to protect the ball bearing E. The air enters by way of the inlet shown in the assembled sketch and passes into the space O, up between the outer and inner spindles and through the small opening P and thence into the cylinder chamber. A fibre washer is used between the stationary connection and the main spindle to seal the air in its passage through the enclosed space. The lower portion is made air tight by means of the gland S; the spindle and gland being additionally supported by the ball bearing T, which is kept in contact with the gland by the action of the coil spring U. The driving bevel pinion V which is secured to the horizontal shaft, engages with the bevel gear W keyed to the vertical spindle D. The central spindle is hollow to allow the free exit of cuttings from the drilled hole.

An application of compressed air for feeding purposes is shown in Fig. 7 adapted to the drilling of the nose on the larger shells. The fixture that supports the shell is of specially heavy construction to avoid any sag when the shell is placed upon the supporting arms so that the bore of the shell will be maintained in a central alignment with the lathe spindle. The turret is locked in a fixed position when drilling, but can be swung to one side to remove or replace a shell. For feeding the work to the drill an air-brake cylinder mounted on a special bracket between the ways of the lathe bed at the left. One of the advantages of this device is the steady and elastic feed obtained with a central supply of compressed air. Considerable skill is required in the movement of the saddle. The feed control is obtained by means of a motorman's brake valve.

## CAMPAIGN FOR FOREIGN BUSINESS IN STEEL IN U. S.

A VIGOROUS campaign for foreign business in steel products is being prosecuted by large export companies in the United States. Representatives of these concerns have been sent to Central and South America. Apparently a precious time to seek foreign business be-

against iron and steel exports by the railroad committee representing the United States Government in an effort to relieve the severe freight congestion at Atlantic terminals and southern ports that has been growing steadily worse for several months. It is estimated that 1,350,000 tons of iron and steel products designed for export are now being held awaiting ships.

The export companies, however, declare that they are not canvassing foreign markets for business requiring early shipments from this country, but that their intention is to cultivate the foreign field with expectation of securing a large volume of business after the war. Incidentally, some business may be secured for shipment within six months if Government licenses should be procurable.

## McGILL UNIVERSITY GIVES VALUABLE AID TO NATION

ON few activities of our national life has war made itself felt so much as on our universities. While the number of students in all classes has suffered an honorable decrease, it is in the engineering and allied technical fields that the most immediately results are found.

McGill University, Montreal, has participated very actively and the work of the students is directed as far as possible toward work of national and military importance. Compulsory military training is now the rule, and every male student who is a British subject is obliged to drill at regular intervals. In addition there is a class for the training of officers, which, although requiring some extra time, is a very important way in which the university can serve the country, the beneficial influence of a university training on an officer's ability being acknowledged in view of the fact that they can acquire the necessary knowledge in a much shorter time than the average person.

All of the McGill laboratories have really been at the disposal of the government for experimental purposes and excellent service has been rendered especially by the physics and chemistry departments. Members of both staffs have devoted a great deal of time to munitions research work as well as the overcoming of the submarine menace, while the difficulties experienced in the industrial world by the cutting off of German trade have received more than ordinary attention from the chemical department with a view to providing for future needs.

The shops under the mechanical department have been placed at the disposal of wounded soldiers for the learning of trades. The Campus has been turned over to the military authorities for drilling purposes and is lighted at the expense of the university when such drills are held. The library has been utilized as far as possible in the distribution of circulating libraries to soldiers' camps and barracks. The physical training course has been featured by the assistance rendered to wounded soldiers in directing massage treatment.

Considerable interest attaches to the work of university men on the several commissions established by the government, and it is interesting to note that two McGill men are on the commission on Scientific and Industrial Research, one of them being the chairman.

### Women's Work

Every organization connected with McGill has done important work in the way of providing comforts for the soldiers and equipment for the men over and above what is given by the government. The largest of these, formed at the beginning of the war, is known as the McGill Women's Union, and is composed of the wives of professors and others more or less intimately connected with the work of the university. The members knit socks, make bandages and many other articles required in the field and hospital and have done really wonderful work.

The honor roll of McGill to date is:

| | |
|---|---|
| Enlistment of students and graduates | 2,200 |
| Honors won | 300 |
| Prisoners | 20 |
| Wounded | 340 |
| Killed | 240 |

## MANUFACTURERS' ASSOCIATION URGE COAL ECONOMY

A CALL to their members to realize the extreme urgency for taking effective measures to reduce coal consumption has been made by the executive committee of the Canadian Manufacturers' Association. In a recent letter Secretary G. M. Murray says: In the light of representations made to your executive committee by the Fuel Controller for Canada, Mr. C. A. Magrath, we feel justified in saying that unless those portions of Canada that are dependent upon the United States for their coal supply voluntarily effect an immediate and substantial saving in their coal consumption, they will be compelled to do so by measures of the most stringent character.

It is idle to take shelter behind the defence that the prices demanded for coal afford all the incentive to economy that is necessary. Notwithstanding the high cost of coal, there is still more or less of it being wasted, in one way or another. The situation is so critical that now even pounds count, and it is a solemn obligation, resting upon every user, to do everything in his power to reduce his consumption.

Unless, as the result of voluntary and united effort in this direction, Canada's requirements are brought down to an irreducible minimum, it is practically certain that a system of priority treatment will have to be set up, if indeed the consumption of coal by non-essential industries is not absolutely prohibited. That is naturally something we all desire to avoid, whatever the cost, but from the present outlook we will only be able to avoid it by doing of our own accord, everything it is humanly possible for us to do, in the way of saving our consumption.

We beg of you, therefore, to take this matter up at once in a practical way.

If natural gas or electrical energy derived from water power is available, please consider seriously the conversion of your plant to its use as a means of relieving the coal situation. If wood or waste can be utilized as a substitute for coal, no matter to how limited an extent, please see that it is used. If anything can be accomplished by co-operating with other manufacturers in your locality and consolidating in one plant work that is now being done in two, please bear in mind that you will be serving the cause of your country by putting up with the inconvenience thereby involved.

The Canadian Manufacturers' Association is now endeavoring to secure technical men whose services will be freely available to manufacturers desiring to co-operate in this all-important movement.

## PREPARATION OF FERRO-URANIUM

BY using pure uranium dioxide, a low-ash coke or charcoal, and a pure iron as raw material, with fluorspar as slag-former in a tilting direct-arc type of furnace fitted with water-cooled magnesite hearth and sides, it should be possible to produce commercially, without a second refining operation, ferro-uranium of any desired content, say 40 to 70 per cent., the carbon content would average less than 2.0 per cent., silicon less than 0.75 per cent., and vanadium less than 0.5 per cent., while aluminum, sulphur, phosphorus and manganese can be kept so low as to be negligible.

The foregoing represents the conclusions arrived at by H. W. Gillett and E. L. Mack from a laboratory study of the preparation of ferro-uranium made by them for the United States Bureau of Mines, published as Technical Paper No. 177.

### Low Power Consumption

The power consumption should be decidedly less than 3 kw. hours per lb. of alloy, and the loss of uranium in the reducing process less than 15 per cent. If experiments show that uranium steels high in uranium are not valuable, but that the presence of the element in small quantities is useful, and if the amount required is so low that the carbon introduced by a high-carbon alloy would be harmless, the furnace might have an uncooled carbon hearth and the alloys would contain 4 to 5 per cent. of carbon.

If uranium is found useful only as a deoxidizer or scavenger of oxygen and nitrogen, aluminum would not be harmful and might be advantageous, and the slag-former might be wholly or in part alumina. As regards the usefulness of uranium in steel, the evidence is somewhat inconclusive and even contradictory. One authority states it has not been shown to add any important properties to steel not obtainable by the use of cheaper elements, and another that some of the large American steel companies that have tried to utilize it have met with little or no success.

### Substitute For Tungsten

There have been various rumors that Germany is using uranium steel liners in big guns, but on the other hand it is known that the stock of uranium compounds obtained from pitchblendes and stored by the Austrian radium works was exhausted early in the war. Experiments made by the Standard Chemical Company in America are said to indicate that a small percentage of uranium may be substituted for a very large percentage of tungsten in high-speed steel without injuring the cutting properties, and that uranium is also useful in carbon steel and cast iron.

A high-speed steel showing excellent cutting qualities contained 0.78 per cent. carbon, no manganese, 0.16 silicon, 0.02 phosphorus, 8.15 tungsten, 3.62 chromium, 1.81 vanadium, and 1.02 uranium. According to other reports, uranium steel with 5 per cent. of tungsten and 3 to 4 per cent. of chromium made a good tool and did good work for, say, two grindings, but after that did not hold its efficiency and had to be re-hardened, while a 40-point carbon steel with 0.3 per cent. of uranium was disappointing, being red-short at ordinary forging heat and altogether uninteresting for practical purposes.

## BEFORE AND AFTER

By N. G. Near.

THE accompanying photographs show how modern equipment is doing away with the dust nuisance in industrial establishments. Fig. 1 shows how ashes were once loaded into a car by means of a clap-trap belt and bucket arrangement. It was often unendurable for the men to work in the vicinity of this loading machine under certain conditions—when the wind was just right and when it was real hot. This view was taken while the steel structure shown in Fig. 2 was being erected. The bottom of this steel structure is visible in Fig. 1.

FIG. 1. BEFORE

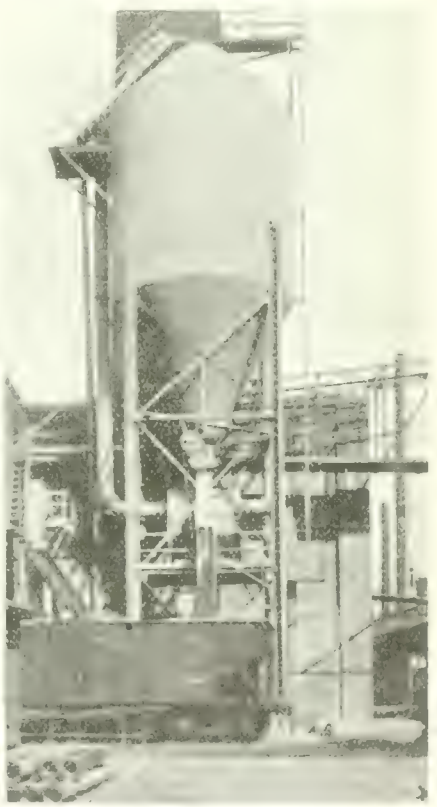

FIG. 2. AFTER

Fig. 2 shows how the ashes are loaded now. There is not a bit of dust, because the ashes are well wetted down by simply turning the valve of a pipe line. The ashes are sucked into the tank in the same way that a vacuum cleaner works, and we all know how dustless vacuum cleaners are. The advance in efficiency is sufficiently obvious to render further comment needless.

## FACTS ABOUT RADIUM

RADIUM is a metal, and has a white metallic lustre; it has been isolated only once or twice, and few people have seen it. Radium is ordinarily obtained in the form of salts, and is usually so sold and used. These salts are all white or nearly white substances, whose appearance is no more remarkable than that of common salt or baking powder.

Radium is found in nature in quantities so exceedingly small that it is never visible even when the material is examined with a powerful microscope. Ordinarily radium ore carries only a small fraction of a grain of radium per ton of material, and radium will never be found in large masses because it is formed by the decay of uranium, a process that is wonderfully slow, and radium itself decays and changes to other elements so rapidly that it is impossible for it to accumulate naturally in visible masses. Radium and radium minerals are not generally luminescent. Tubes containing radium glow from impurities present which the radiations from the radium cause to give light.

Minerals that carry radium are fairly easy to determine, for they affect photographic films in the same way as ordinary light, and they can also be identified by their effect upon an electroscope.—Mining American.

## THERE WAS EFFICIENCY IN THOSE DAYS TOO

By D. A. Hamilton

FIFTEEN or twenty years ago [illegible] would have [illegible] "efficiency" as the same [illegible] to the ratio of work done by to work delivered to a machine. More recent years have put this definition in the background and substituted one that applies rather to motion study—the cutting out of useless moves, the doing of operations in the shortest and best manner possible and it is in this sense that the word has become the most overworked and abused one in our trade. To believe all we are told, we would think that before the day of the efficiency expert our work was done in the slowest and most extravagant manner; some of it was, and some of it may be to-day, and again some of it was turned out in a way to be proud of though at that time it went unheralded and unsung.

The shop that Robert Laing ran was a good example of efficiency as practiced to-day although at that time the success was attributed to Laing's being a "good man." The shop employed twenty to thirty men and did a manufacturing business. Laing was around the shop most of his time, when he wasn't he was working [illegible] board—"so much easier to change a few lines," he would say "than to change a jig." And while at the board, you could often see him with his watch before him, making shadow motions—the motions the drill press hand would have to make in the actual use of the jig under consideration. There were very few of his jigs that did not work out as expected and none of them [illegible] two motions where one would do.

And after the set-up man had gotten a machine ready for an operator, if the job was a new one, Laing would run off a few pieces himself to see if everything was arranged for the operator to really produce. Sometimes a spring could be used to advantage between vise jaws and save a movement with every load. Perhaps he found the parts were so placed on the table beside the machine that the work was all done left handed, perhaps a seat for the operator could be arranged. If [illegible] a "magazine" fixture built that could be loaded while the machine was running. [illegible] presented themselves on drill press work. Pumps and flooding were unknown then but oil or soda water was used and the [illegible] mined by trial—squirt can, wick feed, or [illegible]

parts were so held that when clamps were released, the floor slid back and the drilled piece dropped out and into a box or a [illegible] a chute with a perforated slide that cleaned the work of chips before it landed in the box.

One thing that was carefully watched was to have waiting time eliminated. The men were instructed to inform the foreman a half hour before they were through with a job so that another could be made ready for them. Tools like drills and taps that were used on manufacturing work were always supplied in duplicate or better; then a dull drill or a broken tap would not hold up the production on a job. An endeavor was made to always have a sharp tool ready to replace a dull one. To keep the stream of work flowing, operators were forbidden to "handle" work themselves but had the services of a helper whose sole business was to fetch and carry.

A source of loss in many shops is from men waiting for the floor sweeper. Mr. Laing made a point of having benches and floors cleaned at noon and night when it could be done without interfering with workmen. Unless given permission, operators were not allowed to make any but minor adjustments; these were attended to by the set up man, who also sharpened drills and cutters.

The shop was successful and its success was laid partly to Mr. Laing's being a good man and attending to details but these little things were taken as a matter of course and nothing was ever written about it. Scores of other shops were in the same class. And if a shop to-day followed the plan of these twenty years ago, it would be called "efficient" and its fame would go down with that of the expert who "put in the system."

## DOES A PISTON STOP AT REVERSAL?

By N. G. Near

THE writer has read R. Hamilton's arguments in the Dec. 6 CANADIAN MACHINERY under the above heading with much interest and notes the very clever way in which he endeavors to prove that a piston does not stop at reversal.

A line has no thickness, true enough. It therefore requires no time at all for a crank pin to pass through a line. Therefore, Mr. Hamilton argues the cross head does not stop. That being the case, then, it can be proved that a piston has no "maximum velocity" either. Draw your cross head velocity curve and it will be found that at one "point" the ordinate is longest. The height of that ordinate represents the maximum velocity [illegible] in most of our text books and the writer has always accepted it as being true and must continue to do so. According to Mr. Hamilton's way of looking at it, though, this solitary maximum being represented by a "point" and a point having no magnitude it takes no time at all for the crank pin to pass through that point and therefore the maximum velocity does not exist (theoretically).

I am attempting, you see, to answer Mr. Hamilton's arguments with his own "thunder" and could probably go all the way around the whole path of the crank pin and prove that our understanding of kinematics is all wrong because of the smallness of a point.

To the question, "How long does a piston stop?" there can probably be only one answer—zero seconds. It doesn't stop a hundredth of a second, a thousandth, a millionth, a billionth, or even a decillionth for such stops are all of longer duration than zero. A stop, as is generally understood, means zero velocity and we surely have a "point" in our velocity diagram where the velocity is zero in the same way that we have a "point" where the velocity may be 10 feet per second regardless of whether the cross head is accelerating or decelerating.

Mathematically, let us assume a case where the length of the connecting rod is infinite and the velocity of the crank pin is C feet per second. The velocity of the piston may then be given as $v=C \sin A$ where A is the angle between the crank arm and the line through the shaft and piston. Now, where A is equal to zero the v becomes zero and for that infinitesimally short time the piston STOPS because its velocity is zero. Where the connecting rod is of finite length a similar solution will give the velocity at this "point" as being zero.

True, this may seem like some "pretty fine figuring" and Mr. Hamilton has a strong line of arguments built up on the fact that "zero is nothing" and that if a piston stops zero seconds it doesn't stop at all, which sounds logical because of the play on the words. But everything points to a dead stop via the velocity diagrams and mathematical formulae.

Anything possessing weight must stop before it can be made to reverse "in its tracks" as the expression goes. Even a baseball comes to a dead stop when struck by a bat before it can move in an exactly opposite direction. The bat, when swinging toward the ball, moves at a fairly constant velocity and is little disturbed when it meets the ball because of its greater mass. The whole bat does not stop because its direction is not reversed although some of the fibres in the bat may stop. But the ball DOES stop. The elasticity of the ball permits it to withstand the shock.

Perhaps all "points" in the ball do not stop at once but nevertheless every atom has its own deceleration and acceleration to perform and if the atoms do not function thusly our philosophy is all wrong

## IRON ORE THE BASIC CAUSE OF GREAT WAR

INDISPUTABLE facts which have not suffered even a suggestion of contradiction have been repeatedly stated by various writers regarding the ulterior motive of Germany in precipitating the present conflict. The industrial development of that nation is punctuated by a series of incidents whose continuity and gradually increasing deliberateness leave no room for doubt in the mind of an impartial observer that the war was "planned" in every sense of the word.

Speaking before the National Association of Manufacturers in the States recently, Rev. Newell Dwight Hillis gave a brief resume of known historical facts which throw an interesting light on past events and indicate the future effects on various nations according to the outcome. He said:

"If I understand this war right, it is, essentially, a war for hematite iron ore. It is the greatest war in history, because it is a war for the greatest thing in industrial history, namely steel; without hematite iron and good coking coal you cannot make steel.

"In 1866 Germany was an agricultural people. She had no manufacturing life. All that has its counterpart in your wonderful manufacturing systems in this country did not exist in Germany at that time. First, she captured that coking coal province from Austria. Then she captured Alsace and Lorraine. That was in 1870. But the important thing was this: Germany held a conference of twenty leading men of Germany in Berlin, presided over by Bismarck. In 1866 England led Germany in five things; first in pig iron, second in steel, third in woolen goods, fourth in cotton goods, fifth in the building of ships. In these things Germany was hopelessly behind. Then it was that Bismarck developed his scheme for a world empire that later hypnotized the Kaiser. In 1909 the Kaiser called his ministers together to consider a report presented by the mining engineers of Germany. That report was on the danger which threatened Germany by reason of the exhaustion of her iron supplies. The majority report of the mining engineers said that by 1925, one-half of the factories of Germany would have to shut down for the lack of iron. The minority report gave her thirty years. From this we can understand how desperate Germany was. Then came the discovery of the great iron mines down in Morocco. Fourteen days after the discovery of those mines, Germany had her biggest dreadnought in the harbor of Agadir. Diplomats know it as the Agadir incident. We know how Belgium, Spain, and Portugal united their forces; and how Germany then determined to mobilize her troops the following Monday. Then it was that the business men brought pressure to bear. The Bank of England, the Bank of France, the Rothschild banks, called their loans on the German people, a billion three hundred million dollars. Once more Germany was at bay. She ceased to plan for the mobilization of her troops.

"Some years ago, one of our authors called attention to the discovery of the new iron veins running across Northern France, and containing a great blanket body of hematite ore. It was the most marvelous event in the manufacturing life of Europe during the last one hundred years. The engineers of the French government made borings, and on tracing that ore deposit westward they found it disappearing on the frontier lines of Belgium. When Germany's troops started west in August, 1914, it was to grab that iron ore. Germany went into Belgium to get command of the iron mines of Belgium. A few miles away lay the newly discovered iron mines in northern France. The Prussians fought unto death for the iron mines controlled by that little pass at Verdun. It is said that Germany lost six hundred thousand men in that battle. Why did she make that desperate struggle? For this reason: The little pass of Verdun opens into the great basin of the Brie. From the hour Germany got in there in August, 1914, she began to load every day two or three freight trains with fine hematite ore, and the struggle at Verdun was to control that treasure. For that hematite iron ore Germany is going to fight unto death. The war in South Africa was a gold and diamond war. The war in Mexico to-day is a land war. The war between Russia and Japan was a forest war. This war to-day between Germany and France and Belgium is a war to control the iron mines of Belgium and France, and the coking coal, looking forward to the control of Europe for the next two or three centuries. William Morton Fullerton, in his wonderful book, "Problems of Power," calls attention to the fact that there is enough high grade iron ore now bored in northern France to take care of all the people of Europe for the next three to five hundred years. Germany is going to fight unto death for that iron ore. It is a struggle for steel. Ours is a civilization based upon steel. Steel means locomotives and looms, presses, Pullman palace cars; means enormous wealth for the country through tools and conveniences. As these iron mines go in this war, therefore, so civilization in Europe will go."

## STORING COAL GAS UNDER PRESSURE

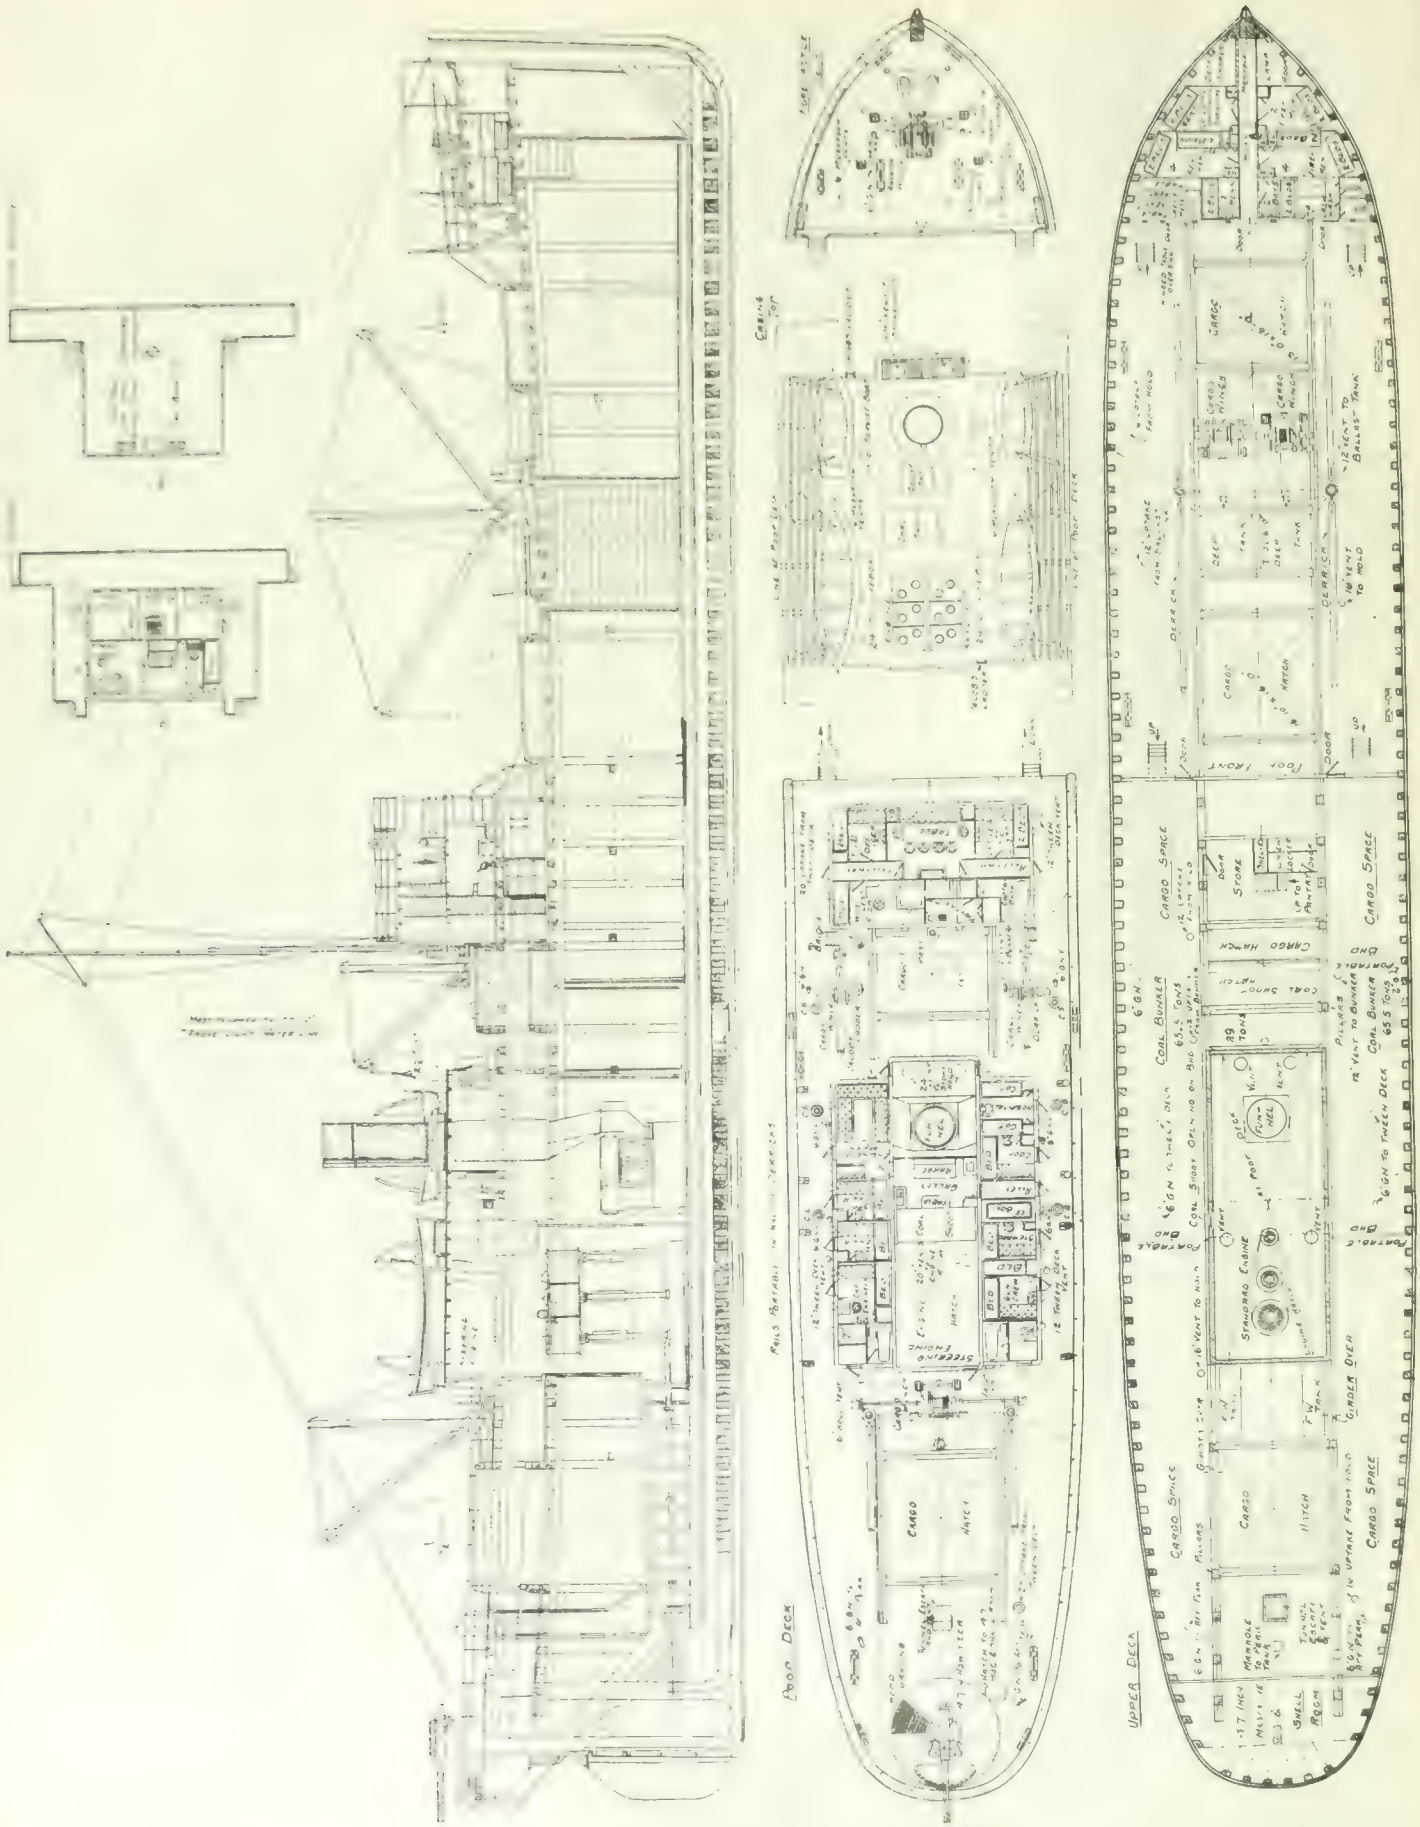
THE rapid development of coal gas as a fuel for motor cars in Britain has been limited by the problem of storage, and much attention is being given to this subject by numerous investigators throughout the country. Fragility and bulkiness are the two principal drawbacks to the extended use of low-pressure containers, consequently attention is being given to the question of compressing it at high presure in cylinders. Coal gas is being regularly compressed to a pressure of 120 atmospheres (about 1,800 lb. per sq. in.), and this must be regarded as the maximum pressure at which the gas can be easily dealt with, though on the continent pressures of over 3,000 lb. per sq. in. are quite common. The great objections to steel cylinders are their dead weight; the care and supervision required in looking after them when stored under high pressures and the liability of the metal to fatigue through constant vibration, necessitating frequent annealing; and the depreciation of the gas by compression, the calorific power being reduced about 10 per cent. by compression to 1,800 lb. per sq. in. Authorities on the subject do not hold out any great hope of steel cylinders ever being adopted universally for compressed gas on motor-vehicles, the opinion of leading experimenters being that the solution of the problem will be found in cylinders made of other metals than steel, or of composite rubber material.

## HUNDRED-POINT MEN

THE need of the hour is emphasized by George A. Simpson, sales manager of the Steel Co. of Canada, who in an able article published on page 19 of this issue presents lucidly, emphatically and conclusively the demands which future business conditions will make upon the industrial personnel of the nation. To derive the fullest benefit from experience, to be able to satisfactorily meet all demands, familiar or unexpected, to sense the future and separate certainty from uncertainty—these and others will be the least of the qualifications imposed on us by the conditions set forth in Mr. Simpson's article.

## GERMANS APPRECIATED SCIENTIFIC EDUCATION

IN the course of a recent discussion on the training of engineers, the eminent English scientist, Prof. W. E. Dalby, said that ten years ago when he went to Charlottenburg in Germany to make some investigations into the training of engineers, there were over 10,000 students of engineering over 18 years of age, who, before they started on their engineering courses, were as well educated as if they had taken an English university degree. In Great Britain he could only find about 900 men to set against the 10,000 of which Germany could boast, and the position of Germany in this respect had probably improved during the intervening years. His own view was that, whatever might be said in regard to the numbers of trained men in British engineering, there was very little wrong with the quality, and he did not hesitate to say there was no country in the world where better engineering training could be given than in British modern university centres. The fundamental need was for the schools to build up a strong pedestal of engineering scientific knowledge, on which could afterwards be constructed an edifice of any specialized knowledge which was desired. To start specialized training in the first place was clearly a mistake.



STANDARD WOOD STEAMSHIPS BUILDING IN CANADA—PROFILE, MAIN DECK, AND ACCOMMODATION PLANS.

# General Specification of Standard Wood Steamships

*By courtesy of the Shipping Department of the Imperial Munitions Board, Ottawa, we are able to place before our readers a comprehensive resumé of the hull and equipment features of the standard wood steam freighters now under construction at various locations on our ocean coasts and inland waterway shores. The text matter in conjunction with the illustrations cannot fail to create the impression that eminently seaworthy and useful craft will be the outcome of this emergency enterprise aside from the non-permanency of the industry.*

WOOD steamship construction on behalf of the Imperial Munitions Board, Ottawa is at the moment being prosecuted with considerable vigor in Eastern and Western Canada. Twenty-seven of the particular type vessel are building in British Columbia and nineteen others are distributed among shipyards between Toronto and the Atlantic seaboard. Leading dimensions of these standardized craft are as follows:

**Hull Dimensions.**

| | |
|---|---|
| Length B.P. | 250 ft. |
| Length O.A. | 259 ft. |
| Breadth, extreme | 43 ft. 6 in. |
| Breadth, moulded | 42 ft. 6 in. |
| Depth, moulded | 25 ft. |
| Depth over keel | 26 ft. 11 in. |
| Draft for displacement | 22 ft. |
| Draft over keel | 21 ft. |
| Approximate deadweight on 20 ft. maximum draft | 2,300 tons |
| Approximate deadweight on 22 ft. maximum draft | 2,800 tons |

**General Description.**

Vessel will be of the single deck cargo type, built principally of Douglas fir, with hold beams, wood deck houses and rails. To have elliptical stern with long poop deck aft, and raised fo'c'sle forward. To have five hatches. One deep ballast tank with longitudinal divisions. To have six watertight wooden bulkheads, one bunker bulkhead, which is a non-watertight bulkhead, one screen bulkhead, and one watertight door between engine room and tunnel.

Accommodation for the officers will be in deck houses erected on the poop deck. A bridge and bridge house will be erected at the forward end of the poop.

Six cargo winches, one of which is to be a warping winch, to be fitted as shown on deck plans. Windlass on the fo'c'sle head suited to handle anchors and full scope of chain, also arranged for warping as usual.

Fore peak to be fitted for fresh water, with filling pipes, suctions, etc. After peak to be fitted in the same manner. Culinary water will be distributed from separate steel tanks of about four hundred gallons capacity each, placed as directed.

The vessel is to be driven by single screw, with engines abaft, amidships, as shown in the drawings. Builders of hull will have no responsibility in connection with the installation of machinery, except in the putting in of foundations for the main engines and auxiliaries, for deck gear, and in the piercing of hull for sea cocks, valves, etc., as directed by the Board's representative, and also in the fastening of deck machinery, deck fittings and windlass.

**Classification.**

[illegible] necessary for a cargo steamer.

**Materials.**

All lumber used in the construction to be British Columbia fir, generally known as Douglas fir, unless otherwise specified. All material to be to the satisfaction of the Board's inspector.

Long lengths are to be used in the keels, keelsons, planking and ceiling, and to be clear of shakes, loose knots and other faults, and, as far as possible free from sap. All decking to be edge grain.

[illegible] drift bolts of galvanized iron and black iron, as hereinafter specified.

**Conditions.**

It is distinctly [illegible] to supply the Board with [illegible] a workmanlike manner, satisfactory for ocean service and fitted [illegible] handling of freight. The work in all departments shall be done under the supervision and subject to the approval of the Board's inspector, and facilities must be afforded him for inspecting material and workmanship during the whole progress of building.

**Drawings and Plans.**

The [illegible] tion with the construction of the vessel will be [illegible] the progress of the work, and if the contractor [illegible] will at once see that he is provided with the necessary details.

**Water-testing of Compartments.**

[illegible] tested with a head of water to [illegible] presentative of the British Board of Trade.

**Keel.**

Keel to be sided 24 in., moulded 20 in. To be in four lengths. Scarphs to be 12 ft. long, and to be copper painted before fastening. The nibs of the scarph to be 4 in. deep. A [illegible] with 1 in. galvanized button head screw bolts, having the heads sunk below the flush for cementing before shoe is fitted. The ends of the scarphs to be spiked.

**Shoe.**

Shoe to be 3 in. fir in approximately 24 ft. lengths, and to be fastened with 8 in. by 7-16 in. galvanized spikes, spaced 15 in. centres, staggered. Heads of spikes to be set in, say ½ in., and cemented.

**Stem.**

Stem to side 18 in. and mould 18 in. The cut water at stem to be reduced to 5 in., and gradually to widen out to conform to the curve of the forefoot as it widens out to meet the keel. The rabbet of stem to be 3½ in. deep. Forefoot connecting stem to the keel to be a wide timber, moulded to the form of stem. The stem as it widens out.

The forefoot to be scarphed to stem and keel, as shown on the stem drawing which will be [illegible]

**Apron.**

Apron to side 24 in. and mould 28. To extend down until it dies on the forefoot. The apron to be connected to the stem with 1½ in. galvanized drift bolts, spaced 12 in. centres, staggered. Forefoot to be connected to stem and keel with at least four 1¼ in. galvanized screw bolts, the heads and nuts sunk below the flush to be cemented on the outside and the recess [illegible]

Balance of the forefoot to be fastened into the [illegible]

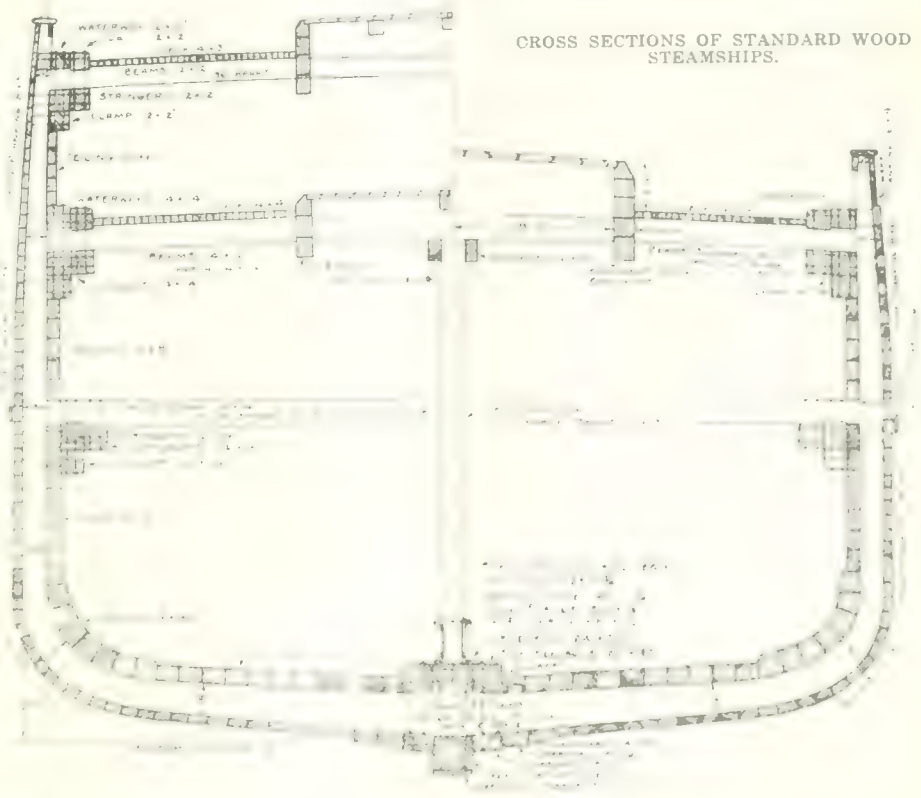
**Propeller Post.**

Propeller post to be moulded 30 in., and generally sided 24 in. In the way of shaft tube, to be swelled out to 32 in., and tapering from the under side of the boss to 17 in. at top of keel, which will be tapered off to suit, finishing at 12 in. at rudder post. Propeller post tenoned into keel and skid log. Copper paint to be applied in mortises before fastening.

**Knee.**

The knee fastening keel to propeller post to be a natural crook, and both arms to be not less than 7 ft., and fitted the full seven feet along keel, the other arm to be fitted to suit height of shaft logs. Rabbett to be 3½ in. deep, and to conform to the table of rabbet measurements, which will be furnished. The keel, propeller post and knee to be fastened to each other with 1¼ in. galvanized screw bolts and drift bolts as approved.

CROSS SECTIONS OF STANDARD WOOD STEAMSHIPS.



and deadwood, as per detail drawing which will be furnished.

**Stem Band.**

An iron stem band to extend from the top of stem to beyond the keel scarph connecting the

**Deadwood Forward and Aft.**

The deadwood forward and aft to be generally [illegible]

**Rudder Post.**

Rudder post to be 24 in. x 24 in., and gradu-

**Skid Log**

**knees in Arch Between Propeller Post and Rudder Post.**

**Plates in Way of Well.**

**To be carried up the post a distance of approxi-**

**Frames.**

**of the top of thick ceiling, 13 in. in way of hold**

**Double frames to be efficiently fastened to one another with fir treenails. In way of the well**

**bulwark stanchion, and care must be taken to**

**ends of the top timbers to be left alone, say**

**be let over the frame for efficient caulking. The**

**servative, also futtock ends.**

**Swash Chocks.**

**The spaces from the lowest salt chocks up to be entirely filled with salt.**

**chain to be freely pulled back and forth. Frames to be spaced 3 in. centres, and to be securely held in place by a sufficient number of carefully disposed ribbands, to hold the frames in place during construction. Frames to be fastened to keel with two 1⅛ in. black drift bolts in each frame.**

**Cant Frames.**

**The heels of cant frames to be closely fitted to the deadwood, and to be securely fastened to**

**Framing at Stern**

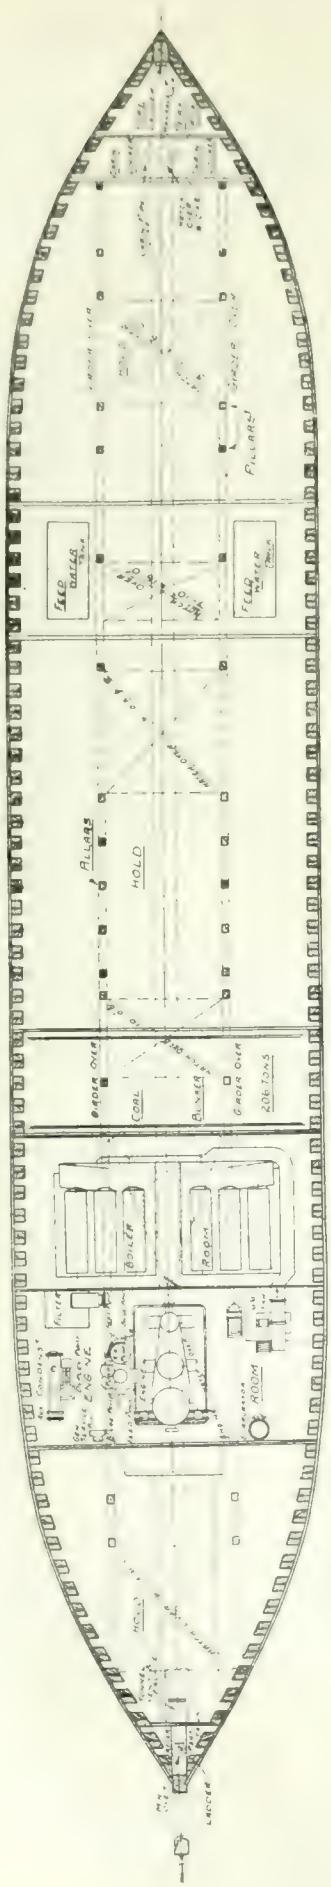
**Keelsons**

**A steel rider keelson is to be fitted on top of the wood keelsons, as shown in cross section. The steel keelson, centre and sister keelsons, frames and keel, have to be fastened with through screw bolts of 1¼ in. galvanized and black iron, as per drawing of fastenings which will be furnished. In addition, the wood keelsons are to be edge bolted with one 1¼ in. screw bolt in each space between frames, as per drawing which will be furnished. Plate washers will be fitted**

**rests on wood. Plate washers will be fitted both under heads and under nuts of edge bolts, as per drawing. The steel keelson will extend from the fore peak bulkhead to the after peak**

**supplied by owners and erected by contractors.**

**Shaft Logs**



STANDARD WOOD STEAMSHIPS BUILDING IN CANADA—SECTIONAL PLAN UNDER MAIN DECK.

**suit shafting, heights of which will be given later. The two sections of shaft logs to be bolted to one another with 1⅛ in. black screw bolts. At the forward end of shaft logs, two hardwood logs, 12 in. x 18 in., are to be fitted running from side to side of vessel, and to be let in over end of shaft log 8 in. To be securely fastened to hull and shaft logs with 1⅛ in. drift bolts. The bolting in the way of propeller post, shaft logs and hardwood cross timbers to be so disposed that in the final boring out of the tube, there will be no iron interfering. The size of tube will be furnished the contractors.**

**Ceiling**

Bottom ceiling to be 12 in. x 10 in., in long lengths, having a limber strake fitted adjacent to the sister keelsons, as shown on midship section. Ceiling to be neatly fitted on edges, so as to lay close, particularly at back. In the way of the deep water tank, the liber strake is to be solid. Ceiling to be edge and face bolted with 1⅛ in. black drift bolts. There are to be four bolts in every plank in every frame, to be driven from the outside and clinched. These bolts to be well headed over clinch rings to prevent drawing. The edge bolts to be 1⅛ in. black drift bolts, spaced about 4 ft. 6 in. centres, and to be long enough to go half way into the next plank but one below.

**Limber Chains**

In the way of the limber strake, chains are to be fitted in lengths which will be indicated on drawings, to be ½ in. chain, short link, galvanized.

**Thick Ceiling in Way of Bilge**

Ceiling in way of bilge to be 14 in. x 14 in., and to be similarly fastened as above.

**Ceiling Above Bilge Ceiling**

Ceiling directly above bilge ceiling to be 12 in. x 10 in., extending to above the hold beam stringers. To be similarly fitted and similarly bolted.

The remainder of ceiling to the under side of maindeck stringers to be 12 in. x 8 in., similarly fitted and fastened.

**Ceiling in 'Tween Decks**

To be 10 in. x 6 in., and to be similarly fitted and similarly fastened.

**Hold Beam Stringers and Clamps**

To be 16 in. x 14 in. and 14 in. x 14 in. To be fastened with 1⅛ in. galvanized screw bolts, four in each frame, through both stringer and clamps, and to be edge bolted with 1¼ in. galvanized screw bolts, through hold beams, four in each end of each beam, and the top and bottom chord to be through edge bolted to one another with 1¼ in. galvanized screw bolts, spaced about 2 ft centres.

**Maindeck Stringer and Clamps**

To be 14 in. x 14 in., similarly fastened to the hold beam clamps, with 1⅛ in. galvanized screw bolts.

**Waterways on Maindeck**

To be 14 in. x 14 in., the inboard waterway to be jogged to the beam as shown on drawings, and to be fastened with two 1⅛ in. galvanized screw bolts, in each frame, and to be through fastened with two 1⅛ in. galvanized screw bolts through frames and outside planking.

Maindeck waterways, stringers and clamps to be edge bolted with one 1¼ in. drift bolt, through waterway, beam, clamps and into ceiling below, and one 1¼ in. screw bolt through waterway, beam and upper and lower chords of clamps, and the inner waterway and inner clamp to be edge bolted with two 1¼ in. bolts.

**Upper Deck Stringer and Clamps**

Upper deck stringer and clamps to be 12 in. x 12 in. To be similarly fastened to maindeck clamps and stringers with 1⅛ in. galvanized screw bolts. To the edge bolted through deck beams and upper and lower clamps with one 1¼ in. drift bolt in each beam at each end, extending into ceiling below, and to have one 1¼ in. galvanized screw bolt in each end of each beam through beam and inner member of clamps.

**Air Spaces**

A 3 in. air course to be fitted for one-fifth of the entire length of the vessel each end, between keelson and hold beam clamps, as shown on midship section. A 3 in. air course the full length of the vessel to be fitted under hold beam clamps as shown on midship section. Between maindeck beams and upper deck beams, chocks 5 in. deep are to be fitted as shown on midship section, leaving air spaces as indicated.

**Outside Planking**

First garboard to be 18 in. x 10 in., with 5 ft. scraphs. Second garboard to be 16 in. x 9 in., and third garboard to be 14 in. x 8 in. Bottom planking to be 12 in. x 6 in., bilge planking to be 10 in x 6 in., side planking to be 8 in. x 6in. up to the guard. Top side planking to be 8 in. x 5 in. Garboard strakes to be fastened with four ⅞ in. galvanized bolts, spaced about 3 in. centres. Bolts to be 32 in. and 20 in. long. The bottom and bilge planking to be fastened with three treenails and a galvanized spike in each frame, and galvanized butt bolts.

The 8 in. x 6 in. and 8 in. x 5 in. planking to be fastened double and single.

Treenails to be driven through and wedged with 1½ in. oak wedges. All short treenails up to 12 in. in length to have a wedge inserted in point before driving. All holes striking iron less than 8 in. in frame to be plugged and another hole bored. All holes above waterline to be plugged. All holes below waterline to be plugged and cemented.

**Guard**

Guard to be 16 in. x 9 in., fitted as shown on midship section, and to be securely fastened to frames with ⅞ in. drift bolts. A hardwood rubbing strake 3 in. x 6 in. to be fitted on face of guard, and securely spiked. Heads of spikes to be driven in and holes plugged.

**Covering Board at Upper Deck**

Covering board to be 5 in. x 18 in., grooved on under side to receive the projecting heads of frames. Covering board to be securely fastened to chocks, frames and outside planking. Covering board to be rounded on outer edge as shown on midship section.

**Rail in Way of Bulwarks**

Rail in way of bulwarks to be 6 in. x 20 in. To be grooved on the under side to receive the heads of stanchions. To be rounded both on the inner and outer edges as shown on midship section. A 3 in. x 9 in. fore and aft plate to be fitted under the rail, and to be well fastened to stanchions and rail with spikes.

**Beams**

Hold beams to be 14 in. x 14 in., spaced as shown on inboard profile. To be secured to clamps and stringers with screw bolts as already described.

**Main Deck Beams**

To be 14 in. x 14 in., at amidships, running to 10 in. x 14 in. at ends, 5 in. worked and 4 in. sprung, spacing 36 in. Detail of beam ends will be furnished. Beams to have a camber of 9 in. amidships. Beams in way of hatches to be 14 in. x 15 in. from forward to the after end of engine room casing. Aft of the engine room casing, main deck beams will be 12 in. x 14 in., and hatch beams 14 in. x 14 in.

Upper deck beams to be 12 in.x 12 in., 36 in. centres, and beams in way of hatches to be the same width as the corresponding hatch beams below, by 12 in. deep.

**Main Deck Hatch Coamings**

Main deck hatch coamings to be 12 in. x 14 in. and to be notched into beams in way of hatches a distance of 2¾ in., as indicated on midship section and details.

Carlins in way of hatches to be notched into coamings 2¾ in. as indicated on drawings.

Four 2 in. rods with plate washers and turnbuckles to be fitted in hatchway at each side, as indicated on drawings.

**Upper Deck Hatch Coamings**

Upper deck hatch coamings to be 12 in. x 12 in., notched into deck beams in a similar manner to main deck. Carlins in way of upper deck hatches to be notched into coaming in similar manner to main deck beams. Upper deck beams and carlins to continue to outside of frame as shown on midship section, the heads of frames being notched out for this purpose.

**Lodging Knees**

Carlins to be secured to hatch coamings by lodging knees 8 in. deep, fitted as shown on drawings. To be thoroughly bolted to both carlins and hatch coamings with 1⅛ in. drift bolts, clinched.

**Continuous Stringer Under Main Deck Beams**

A continuous fore and aft stringer to run under deck beams below hatch coamings. To be 12 in. x 14 in.; to be scarphed with 5 ft. scarphs. Scarphs to be fastened with 1 in. black screw bolts and stringer to be securely bolted to beams with 1⅛ in. drift bolts, two bolts in every beam.

**Side Keelsons**

Two side keelsons 12 in. x 16 in. to be fitted to ceiling directly under the continuous stringer and to be continuous. To be scarphed, and secured with 1 in. screw bolts.

**Continuous Stringer Under Upper Deck**

Continuous stringer under upper deck to be 10 in. x 12 in., and scarphed and fastened to deck beams in similar manner as main deck stringer.

**Pillars**

Quarter pillars 12 in. x 12 in. to be fitted between the slide keelson and the continuous stringer under main deck beams. Pillars to be as shown on inboard profile. The heels and heads of pillars to have hardwood bearing strips fitted. Hardwood to be 5 in. thick at heel and 3 in. thick at head. Pillars to be secured to side keelson at heel with plate straps ½ in. x 12 in., 3 ft. 6 in. long, securely bolted to one another and to pillars. Heads of pillars to be fastened with an 8 in. knee each side of pillar. Knee to be securely fastened to pillars and to stringer with 1⅛ in. black drift bolts.

**Upper Deck Pillars**

To be 4 in. x 5 in., extending from top of continuous coaming in main deck to underside of stringer on upper deck. Pillars to be fastened as shown on inboard profile.

**Continuous Coaming on Main Deck**

To be constructed of three courses of 12 in. x 12 in., in way of hatches, and two courses between hatches as indicated on midship section. Lower member to rest on top of beams and hatch coamings, and all to be securely bolted to beams and to one another with 1⅛ in. black drift bolts. Top member of coaming in way of hatches to be notched out for hatch cover, as indicated on midship section.

**Cross Coamings on Main Deck**

Cross coamings in way of hatches to be laid on top of desk, and to be 12 in. thick at bottom; the upper courses are narrowed to form landing for fore and after. See detail.

**Upper Deck Hatch Coamings**

To be similarly constructed to main deck coamings and similarly fastened. To be in two courses of 10 in. x 12 in. Upper courses to be notched for hatch covers in a similar manner to main deck hatches. These coamings only run two beam spaces beyond the hatch opening. Cross coamings to be similarly fitted on top of deck to those on main deck.

**Hatchways**

All hatchways to be lined with ⅛ in. steel plate with a 2 in. half-round chafing iron at bottom. The 2 in. half-round chafing iron in a fore and aft direction will not register with the one running athwartships, as the continuous stringer under the deck beams running fore and aft make the whole coaming at side deeper than at ends. In order to keep a line from fouling, the half-rounds on the fore and afters are carried beyond the ends of hatches at both ends, for a distance of 2 ft., as will be indicated on drawings.

**Hatch Shifting Beams**

Shifting beams 18 in. x 14 in. to be fitted in hatchway as shown on drawings. A ½ in. x 7 in. stirrup plate is to be fitted at ends of shifting bases and the ends of shifting beam will rest in angle sockets. There will be bearing plates ½ in. thick fitted on top of shifting beam to receive the fore and afters.

**Hatch Fore and Afters**

Hatch fore and afters to be one 18 in. x 16 in. notched out at top for covers, and two 14 in. x 14 in., tapered to suit the rake of covers. These fore and afters will have ½ in. x 7 stirrup plates fitted on the ends, and they will rest on bearing plates fitted on the cross coaming. The ends of the fore and afters will rest in single sockets. See detail.

**Wood Hatch Covers**

To be 3 in. thick and constructed out of two pieces 5½ in. x 13 in., through bolted to one another with three ⅝ in. bars clinched in the usual manner. These bars are to be driven as indicated in detail, so that the bars may form the means of breaking away the hatches as well as the means of lifting the covers off.

**Hatch Cleats and Battens**

Hatches to be fitted with cleats spaced 2 ft. centres, and to be fitted with bottoms at least ⅞ in. thick, and the usual wedges, as shown in detail.

**Deep Tank Hatches**

Deep tank hatches are to fitted with one course of 12 in. x 12 in., and 8 in. x 5 in. channel bars on top of the 12 in. x 12., with ⅝ in. steel watertight covers as will be shown in detailed drawings.

**Bulkheads**

There will be four ordinary watertight bulkheads, one forward of bunker, one at the after end of engine room, one at the after end of bunker and at the collision bulkhead. These are to be constructed of two thicknesses of 3 in. lumber, laid diagonally and fitted between the two diagonal courses with canvas, painted with marine glue, to approval. The boundary timbers will be 7 in. x 7 in., fitted on both sides of the bulkhead and the vertical stiffeners will be of timber 3 in. x 5 in. spaced 18 in. centres. These bulkheads are to be made watertight, and the details of construction will be furnished. There will be a bulkhead at the after end of bunker which will be similarly constructed, but having no canvas between the courses. This bulkhead will be fitted with the necessary openings for access to coal. The vertical stiffeners instead of being spaced 18 in. apart will be 30 in. apart. In addition to the above, there will be constructed two special bulkheads fitted as a deep tank. These will be constructed of two thicknesses of 4 in. lumber, laid diagonally with canvas between, arranged to approval. The boundaries will be 7 in. x 7 in. fitted on both sides of the bulkhead, and the wood stiffeners will be [illegible] in. spaced 18 in. centres. These bulkheads will be furnished. In the deep tank, a fore and aft centre line bulkhead will be constructed of 8 in. lumber, fitted with lightening holes. The construction of these bulkheads will be detailed. Fore and aft bulkhead will be fastened with drift bolts, and the other bulkheads will be fastened with spikes, to approval. Screen bulkheads to be fitted as and where directed.

**Decking**

Main deck planking will be 5 in. x 5 in., finishing [illegible] edge grain fir. The upper deck will be 4 in. x 4 in. [illegible] straight edge grain fir. The main deck to be fastened with 7/16 in. x 8 in. galvanized spikes, two in each strake in each beam. The upper deck to be fastened with ⅜ in. x 7 in. spikes, two in each strake in each beam. These spikes to be reeled and plugged, with plugs set in [illegible] and 40 ft., averaging 30 ft., and should be cut as soon as possible for air drying before being laid. The edges of decking to be bevelled for caulking, care being taken that the bevels leave the vertical grain up. Decks to be payed with marine glue.

**Pointers**

Two sets of pointers forward, and two sets aft to be located in suitable positions to give strength. To be 12 in. x 18 in. in order to mould to a suitable size. To be connected at heels with a natural crook. Pointers to be fastened with 1⅛ in. drift bolts. Six bolts to be in every frame, clinched, and all bolts to be driven before outside planking is put on. Pointers should span four frames.

**Breast Hooks**

To be natural knees fitted forward 12 in. thick, to approval. Arms to be long enough to provide efficient fastening through frame. Throats of hooks to be well fastened into stem with 1½ in. bolts and face of arms to have ten 1¼ in. bolts, and bolts to be clinched.

**Knees**

Knees will be fitted at head of hold pillars. [illegible] other arm 3 ft. long. Similar sizes knees will be fitted as lodging knees in the way of all openings, and similar knees both hanging and lodging, will be fitted in way of continuous stringer under deck. Hanging knees will be fitted under the fo'c'sle deck beams at ends. These knees to be 10 in. knees, length of one arm 3 ft. and the other arm 4 ft. The knees will be fastened with 1⅛ in. drift bolts, clinched. Hold beam lodging knees to be fitted as directed, length of one arm 3 ft. and the other arm 4 ft. Knees to be 6 in. at ends, and 18 in. at throat. Knees to be 12 in.

**Knightheads**

Knightheads to be fitted in way of stem and stern for a distance of approximately 6 ft. 6 in., as indicated on drawing.

**Horn Timbers**

Horn timbers to extend from deadwood to after end of vessel. To be two in number 12 in. x 12 in. To be securely fastened to skid log, rudder post and frames, all to approval. Filling-in pieces to be fitted between horn timbers and skid log. Fastening to be 1⅛ in. drift bolts.

**Construction in Way of Engine and Boiler Room**

Spaces between floors in way of engine and part of boiler room will be filled in solid from long floor to long floor timber and the lower edge of these filling pieces should be bevelled off to allow water to run to limbers, and in addition thereto, fore and aft timber will be fitted to the height of the top of steel rider keelson, extending from after bunker bulkhead to bulkhead at after end of engine room. The fastening of this timber is to be governed in large measure by the holding down bolts necessary for the engine bed, so as to clear holding down bolts. Fastening to be 1⅛ in. black drift bolts. Floor in engine room to be sheathed with 5 lb. lead and boiler floor with bricks.

The fore and aft timbers in the engine and boiler room are aranged to form engine and thrust seating, details of which will be furnished.

**Decking Over Shaft Tunnel**

[illegible]

**Deck Beams Over Tunnel**

To be 6 in. x 6 in., spaced 3 ft., supported with 6 in. x 6 in. pillars, one pillar on every beam and four rows of pillars to be fitted if possible.

Seatings for tunnel bearings to be fitted in tunnel as directed.

**Bulkhead at Forward End of Poop**

[illegible] indicated on drawing. There will be an opening [illegible]

**Bulkhead in After End of Fo'c'sle**

This bulkhead to be built of solid 5 in. lumber. There will be openings in this bulkhead for access to the fo'c'sle. Details of these will [illegible]

**Casing Around Engine and Boiler**

[illegible] 'tween decks will be built of solid 4 in. lumber. [illegible]

**Chain Locker**

A chain locker to be fitted as shown on drawings aft of the collision bulkhead. To be of such size as will safely stow the chain. Eye plates for securing the ends of cable to be fitted in chain locker.

**Small Hatches**

Small hatches to be fitted to give access to the fore peak bulkhead, chain locker and after peak bulkhead.

Ladders

Watertight Door

Ferrous Parts

Construction of Fo'c'sle Head

Ventilators

ventilation, an air space will be left in the way of the bunkers in the strake of ceiling one below the bottom of this air space. The floors in the way of bunker will be leveled to the top of the wood side keelsons under heels of pillars, and covered with sheet iron.

**Hawse Pipes**

Hawse pipes to be fitted for stockless anchors as per drawing which will be furnished. To have chafing ring on deck and cover plate.

**Chain Stopper**

A chain stopper will be fitted in a suitable location for the cable.

**Devil's Claw**

A devil's claw will be fitted for the anchor cable. Detail will be furnished.

**Rudder**

A steel rudder to be fitted with steel lock

SHIPYARD PLANT OF THE FOUNDATION CO AT VICTORIA, B.C.

**Caulking**

All outside planking to be caulked with best hand-picked oakum. Caulking to be in the proportion of one strand of oakum to each inch thickness of plank. Caulking must be well horsed and carefully done. Outside plank seams up to 10 ft. waterline to be cemented. Balance of outside seams to be puttied. Decks to be caulked with the best hand-picked oakum, in the proportion of one strand of oakum to each inch thickness of plan. To be well horsed, seams to be payed with marine glue to approval. Ceiling in way of deep ballast tank to be caulked so as to be watertight. All watertight bulkheads to be caulked where necessary, to ensure watertightness. The whole of the caulking throughout the entire vessel must be first-class in every respect, and each strand must be well hardened up before the next strand is laid.

**Fastenings**

Vessel to be efficiently fastened in every respect, and the fastening to conform generally to the sizes stated in the various items hereinbefore mentioned.

as indicated on drawings, and in way of deep tank, swan-neck ventilators to be fitted as indicated on drawings.

**Hawser Pipes, Fair-leads and Bollards**

Hawser pipes, fair-leads and bollards to be fitted as indicated on drawings, and to be securely fastened.

**Ports**

Port lights to be fitted in fo'c'sle as directed. These lights to have 10 in. clear glass.

**Accommodation Ladder**

Accommodation ladder with all fittings, tackle and gear necessary for shipping ladder on either side of vessel. Ladder to be made of wood. All fittings to be galvanized. Suitable platforms with necessary fittings to be provided for landings. Ladder can be made in two sections if required.

**Beds For Windlass, Winches and Steering Engine**

Beds for windlass, winches and steering engine to be laid as directed, and to approval. Any extra stiffening required in way of these to be fitted as directed.

having steel gudgeons and pintles. Gudgeons to be lined with lignum-vitae, all as per drawing which will be furnished.

**Machinery Spaces**

Machinery spaces are to be lined with ⅛ in. wrought iron, properly secured, in the way of all parts of woodwork exposed to risk of fire. In general terms, the stokehold will require to be completely sheathed and such parts of the engine room as will be indicated by the Board's Inspector.

**Scuppers**

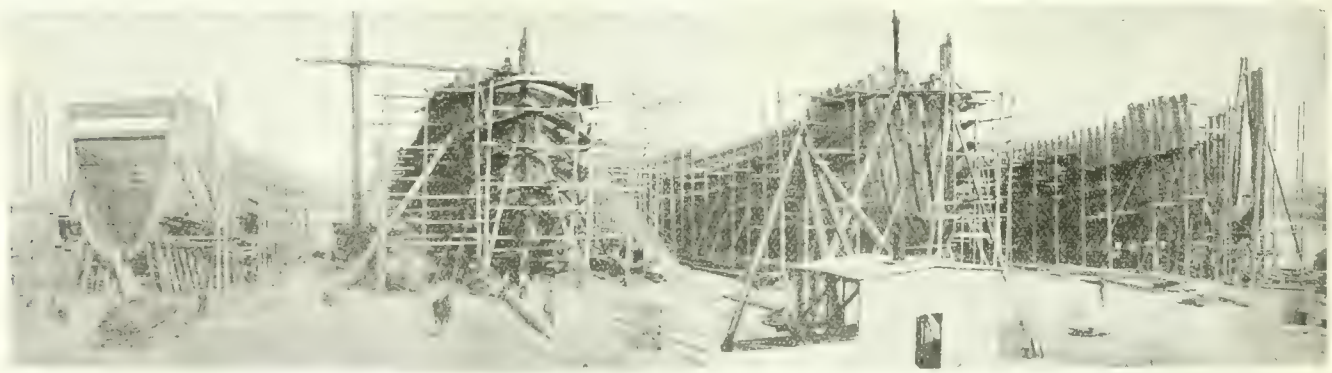
Scuppers to be led through waterway as indicated on drawings. Of lead pipe 4 in. in diameter. To be flanged both outside and inside and securely fastened with galvanized clout nails.

**Accommodation For Crew**

Accommodation for crew to be fitted in fo'c'sle as indicated on drawings. To be plainly but substantially built, and to have suitable lockers fitted. Berths to be open iron berths of suitable pattern.

**Chain Pipes**

Chain pipes to be led through fo'c'sle in proper



[illegible] CONSTRUCTION AT THE YARD OF THE FOUNDATION CO., VICTORIA B.C.

**Masts**

Two pole masts or derrick posts as arranged to be fitted of a suitable diameter, to carry sets of derricks capable of handling five tons. If masts are fitted, all mast irons, irons for derrick heels, rigging, rigging screws, chain plates, forestays and backstays to be fitted to approval, and as indicated on drawings. Masts to be

All mast irons and other blacksmith work will

contractor.

in solid 5 ft. each side of the mast, and pieces being let into the adjacent beams. These filling-

**Beds For Auxiliary Machinery, Etc.**

To be installed and fitted as and where directed.

**Bunker Spaces**

Bunker spaces to be lined with 1¼ in. ceiling [illegible] This ceiling to be covered with ⅛ in. black iron sheets, to protect same. All spaces intenuded for use as bunkers to be so fitted with air spaces and sheeting. Ventilation of bunkers to be very closely considered and carried out to approval. Sides of bunker below hold beam clamps will have air space shown on midship section immediately below the clamp as a means of ventilation. The 3 in. air space will not be worked around the hold beam clamps, but will cease directly under the clamp. Air space above the clamp will

location to suit windlass. To be of sufficient diameter to allow chain to stow freely. Drawings of this will be furnished.

**Plumbing the Fo'c'sle**

Plumbing in fo'c'sle will be plain but substantial, and great care must be taken with this particular work.

**Coaming on Top of Covering Board Around Upper Deck**

A coaming 4 in. x 6 in. to be fitted on top of covering board as shown on midship section, to receive stanchions.

**Joiner Work**

Accommodation for officers, and officers' dining room and pantry, to be erected as shown on plan. Officers' and engineer' rooms to be fitted in good cargo boat style. Rooms to be fitted

with spring berths, hardwood front, upholstered settee, desk, drawers and folding lavatory. Floor laid with linoleum and carpet runner

Dining saloon to be panelled in hardwood and fitted with tables, swivel chairs, sideboards, etc., as usual in vessels of this class. Pantry to be fitted up with hot press and all necessary shelving. Details of the construction of this house will be furnished.

In the way of engine room casing, galley, crew's messroom, storerooms, ice house, officers' bath and W.C., engineers' bath and W.C., petty officers' bath and W.C., wireless room, room for cook and boy, and room for petty officers, will be fitted. Galley will be lined with galvanized iron, fitted on [illegible], leaving an air space all round. Galley to be fitted with stove shelving and all necessary fittings. Galley funnel to be fitted as directed.

**Crew's Messroom**

Crew's messroom to be fitted in plain manner, with [illegible] and all necessary shelving.

**Storerooms**

Storeroom to be fitted aft on main deck. To be [illegible]. Storeroom on upper deck to be fitted with drawers and [illegible].

**Ice Box**

Ice box to be fitted and properly insulated. Shelves to be constructed with galvanized iron, and all [illegible].

**Baths and W. C.**

To be provided for officers and engineers, with water supply, etc., to approval. Plumbing must be efficiently and carefully done.

**Wireless Room**

Wireless room to be fitted with berth, drawers, etc., similar to officers' rooms.

**Petty Officers' Rooms**

To be fitted with [illegible], etc., plainly but substantially built. Rooms for gun crew to be fitted aft on main deck as indicated on drawings. To be fitted with [illegible] drawers, settees and folding lavatories as directed.

**Port Lights**

Port lights [illegible] to be brass throughout, showing 14 in. clear glass, and lights in the way of engine room casing to be of iron body with brass frame, showing 12 in. clear glass.

**Engine Room Casing in Way of Rooms**

To be built as indicated on drawings, detail of which will be furnished. Bulkheads between rooms will be double tongue and groove, laid diagonally, as will be shown in detail.

Back beams and carlins over accommodation will be [illegible] in. x 3 in., spaced not over 21 in. centres, and arranged so that deck beam, outside stud, stud in engine casing, and coaming will all register in way of bulkheads, so that bulkhead can be securely fastened and set as a brace.

**Stanchions**

4 in. turned stanchions to be fitted around poop and fo'c'sle decks, spaced generally 4 ft. centres. Short stanchions running to rail to have hole bored through centre to allow a 5/8 in. rod to pass through. Long stanchions running to the deck will have through rods fitted where directed alongside stanchions. Short stanchion rods are bolted through rail, coiling and covering board. Long stanchions rods bolted through plates, rail, ceiling and covering board. Plate at head of stanchions to be 4 in. x 6 in. The ends of carlins and deck beams to be dovetailed into place as will be shown on details.

**Rail**

A suitable rail to be fitted having fore and aft runners between rail and deck as shown in drawings.

**Decking Over Accommodation**

To be 1½ in. T. & G. 3¼ in. face, planed smooth- V-jointed on the under side, and to be covered with felting and canvas. Canvas to be No. 2, having drilling bedded in white lead under the joints of canvas. Joints of adjacent strips of canvas to be closely butted over drilling and to be nailed with double pointed galvanized tacks, spaced about ¾ in. apart. Canvas to be thoroughly stretched before being nailed. This work must be carefully done in order to ensure a tight deck.

Immediately canvas is laid, it should receive a coat of paint, and should receive in all four coats of paint. Covering board for canvas to be [illegible] in. [illegible] and [illegible] Waterway in way of covering board to be laid in [illegible].

**Skylights**

Skylights for engine room to be built of teakwood [illegible] with approved opening gear.

**Ventilators**

Ventilators [illegible] ventilators, [illegible] and [illegible].

**Bunker Rings**

Bunker rings to be fitted [illegible], as shown on drawing, and to detail.

**Coal Chutes**

Coal chutes to be fitted in engine room casing as directed, with suitable doors for coaling 'tween decks. Detail will be supplied. The [illegible] boiler casing fitted [illegible] on drawings.

**Fidley Top**

To be constructed as directed. To be fitted with angles and gratings, according to drawings which will be furnished.

**Stokehold Ventilators**

Stokehold ventilators of ample diameter to be fitted as directed and to have approved turning [illegible].

**Engine Room Ventilators**

Ventilators [illegible] to be fitted [illegible] as directed [illegible].

**Bridge, Pilot House and Captain's Room**

A [illegible] modation, with pilot house, captain's room and sitting room, and chart room erected thereon. The whole of this work to be built to detail, which will be furnished.

**Rail Around Bridge**

A [illegible]

In the erection of the pilot house and officers' rooms below, care must be taken that no iron fastening of any kind is used, within a radius of 12 ft. of the compass.

**Davits**

Davits to be fitted suitable for the boats they have to carry. Steps, cranes and all gear necessary for the correct fitting of the davits to the [illegible] blocks and life lines required by the Board of Steamship Inspection and the Board of Trade. There will be [illegible] boats, one on each side of the vessel, and one set of davits on one side for an approved working boat. Davits will be furnished by the Board.

**Boats**

Two Class A life boats to the British Board of Trade requirements to be fitted, one on each side of the vessel, of dimensions required by regulations. Each boat to be capable of taking the whole of the crew of the vessel. A service [illegible] vessel, and built to satisfy Class X requirements of the Board of Trade. Boats to be supported in davits to the requirements of the Classification Society, fitted with all necessary gear and rigging for handling same. Boats to be furnished by the Board.

**Boat Chocks**

Suitable [illegible] as directed and to detail.

**Anchors and Cable**

Vessel to be fitted with anchors and cables to the requirements of the Classification rules. Anchors to be of the stockless self-tripping class, of approved manufacture, and of weight required by rules. Cable to be of stud link type, to classification requirements, and to stow in [illegible] peak, which locker is to be fitted with drain to bilges. All to be furnished by the Board.

**Steering Engine**

Steering engine of approved make to be arranged directly over the rudder, with all necessary pulleys, chains, quadrants, etc., as required, to give the desired leads, and to be fittted with suitable hand gear. Control rods to be laid from the steering engine to the steering wheel on bridge, all as per drawings which will be furnished.

A house to be built over the steering engine, [illegible] seating on deck. Details of this house construction will be furnished.

**Ladders, Etc.**

All deck ladders to be built of hardwood, fitted with cast iron treads, and toeplates, and secured by galvanized iron fastenings. Ladder rails to be galvanized iron pipe. Ladders to be fitted as and where directed, in accordance with general arrangement plan. Accommodation ladder, wooden hold ladders and Jacob's ladder, etc., to be supplied as hereinbefore mentioned.

**Deck Storerooms**

To be fitted with all necessary shelves, hooks, and cleats for tackle, etc.

**Lamp Room**

[illegible]

**Side Light Screens**

[illegible]

**Carving**

Vessel's name, and Port of Registry to be carved on the stern, and vessel's name to be carved on the bow. Same to be also painted on boats, life buoys, bells, etc. The [illegible] carving [illegible].

**Ship's Bell**

A [illegible] where directed.

**Binnacles**

[illegible]

**Aerials**

Aerials for wireless and lead to wireless room [illegible].

**Heating**

[illegible] fitted in accommodations with approved radiators [illegible].

**Electric Light**

A [illegible] capacity driven by a turbine to be installed, with all fittings complete. To be laid out in suitable circuits. To have switchboard with double pole switches, ammeter, voltmeter and short circuit indicator. Sockets to conform to British standard thread and to be of the bayonet [illegible].

**Pumping**

A [illegible]

**Scuppers**

[illegible] accommodation and boat decks, all to approval.

**Compasses**

Stands for compass and steering wheel in pilot house, to be fitted as and where directed. Standard compass to be installed as and where directed.

**Fire Service**

A fire service to be fitted as arranged, and all fittings necessary for steam heating, pumping arrangements and fire service, to be installed as and where directed. A wash desk service to be fitted to the fire service as directed.

**Tanks**

Two fresh water tanks to be installed on boat deck as directed, of about four hundred gallons capacity each, with suction to the galley only. Additional fresh water tanks to be fitted in the wings of tunnel, having all necessary seating, etc., fitted as and where directed. These tanks to connect to pumps for boiler feed. Deck fittings for filling pipes, etc., to be fitted as and where directed.

**Painting**

Outside planking below load waterline to be painted two coats of copper paint. All above load waterline to have three coats of lead, and finished navy gray. All interior work to have three coats of lead paint. Interior accommodation to be finished with colors approved by the Board, varnished or polished as found necessary. All deck work, fittings, etc., to be finished navy gray. Inside of decks, clamps, etc., to be oiled and all projecting ends of fastenings and visible iron work, including steel keelson, to be painted red oxide paint.

**General**

It is to be understood that while in this specification, reference is made to winches, windlasses, hawser pipes, fair-leads, bollards, hawse pipes, steam heating, pumping and fire service, etc., the contractor will only do the necessary work to allow of their being installed, such as making beds, boring holes for holding down bolts, etc. The workmanship must be first-class of its kind, and all work must receive the approval of the Board's representative. All lumber exposed both inside and outside to be dressed, except the sides of the sister keelsons.

This specification does not include any equipment, ship or engine supplies, deck or engine fittings, but it is to be understood that storerooms are to be fitted for supplies on deck and in engine room, as directed, and that all fittings supplied by the Board will be installed as directed.

## RECLAIMING SCRAP METAL

A NEW method for the reclamation of [illegible] Thomas, Mich. By this method all scrap including broken and obsolete parts of locomotive and car equipment, nuts, bolts and old chains, are forged into commercial steel again. The scrap is piled on wooden boards, 14 inches square, in piles of from 300 to 350 pounds. It is then charged into a crude oil furnace, where it is brought to a welding heat, after which it is taken from the furnace with a crane and grab tongs and placed under a 7,000-pound steam hammer and forged into slabs 15x2½ inches and 3 feet long.

The saving created by the introduction of this method is considerable, and [illegible] times, when metal is difficult to obtain at any price.

The work is under the direction of Paul H. Cain, the foreman of the forge shop, who came to St. Thomas from the Beech Grove shops of the Big Four Rail-

## PURPOSE AND METHODS OF INSPECTION*

IN considering why inspection is necessary a consideration of the various classes of men employed in production will be helpful. Apart from laborers, there are in average engineering works a majority of workers, male and female, who, although graded as mechanics, are practically repetition workers. It is not necessary for them to have the training and knowledge of the higher grade engineer, and the more progress is made with the introduction of automatic machines and a general system of repetition work the more will it be possible to use less highly skilled labor. Again, the engineer puts forward a design and the drawing office works it out in detail. The drawings should be reproduced as shop drawings, showing the various processes for each part, and clearly laying down the limits which are to be worked to and the material from which the parts are to be made.

The producer—i.e., the mechanic, cannot be expected to have the knowledge required to determine whether the material is in accordance with the specification, and if the material be slightly above or below the limits of the specification it is impossible for him to determine whether it is safe to employ it. The designer, however, may justly be entitled to expect that a finished article is in accordance with his wishes, else he can hardly be held responsible for its correct functioning. Some department must, therefore, exist to take this responsibility, and an inspection branch is essential for the purpose.

### The Production Aspect

From the machine shop point of view the workman desires output because it gives him more money; the foreman desires it because therein lies his chance of promotion; the production manager may thus be said to be the enemy of the designer. The directors and shareholders of a company must, therefore, protect themselves from bad workmanship; the reputation of the firm must be upheld, and the finished article must be as good as possible, having due regard to prime cost. Inspection alone will ensure this.

Again, inspection of a finished part is essential before assembly of all the parts into the whole. A well-organized shop with a proper system of inspection results in a saving of time and money in erection. In many cases where the viewing of the output of the machine shop is slack, or is lacking, erection becomes practically hand-fitting, interchangeability is entirely lost, and spare parts are impossible to fit. An organization is, therefore, required on the lines of a small [illegible] to deal with all goods in the receiving or inward store (nothing being allowed to go forward to the machine shop unless it bears the stamp of that inspection branch), and a complete [illegible] in the machine shop and in a view room between the machine shop and what may be called the erection or main store.

### Interests of the Purchaser

The average purchaser is content to take a firm's guarantee that the goods supplied are in accordance with the order. He usually protects himself by seeing that the goods are externally correct, and that they function reasonably in accordance with his requirements. Government departments go a good deal further. They are responsible for public funds and have to ensure that value is obtained for the money expended. In many cases the requirements may be of a special naval or military nature of which the contractor has little or no knowledge. Inspection from this point of view may be divided into two main classes—final inspection and detailed process inspection. The former is possible in many cases—for example, in the purchase of a lathe. Detail inspection is essential where the nature of the material is of vital importance in the functioning of the whole, as when the factor of safety is low.

Detailed inspection during manufacture should not be necessary when a firm has a good view room of its own. In this case material must be inspected on or before entering the works. Steel should be inspected where it is made, at the steel works or the rolling mills. Any faulty material is then at once thrown out, and the steelmaker has the opportunity of tracing the trouble to its source. Freight to and from the steelmakers' and contractors' works is saved; in fact, a double journey is obviated, as faulty material will probably be returned to the maker by the contractor.

The next place where the inspection department picks up the thread is where the parts have left the machine shop. Here the amount of inspection necessary depends entirely upon the firm. In the case of a good maker who is erecting, say, 80 per cent. of his products into finished machines and sending away the remainder as spares, it would probably be necessary for the Government inspector to inspect only the spares, the machines themselves being inspected after erection. A running test, if one is required, is carried out under the supervision of an inspector, and at its conclusion a careful examination is made to see that no parts are unduly worn or fail in their action.

### Women Inspectors

Women are quick to learn elementary details; thus they can be taught to use micrometers intelligently, and easily manage the "go" and "not go" gauge. But with such a training they cannot be given discretionary powers to any extent. The most economical way to employ them is to place an inspector with discretionary powers over a gang; all doubtful cases are submitted to him and he carefully scrutinizes the rejections to ascertain that they are necessary. Where the amount of work is large and numbers of girls are employed, the rejections should be gone over by a specially appointed inspector, as many of the parts rejected by women viewers can be made use of for production purposes, either by alteration or by selective assembly.

Of women employed on routine work inspection some show greater aptitude and intelligence than others, and these certainly make excellent inspectors. With one or two exceptions, however, they do not, as experience shows, approach the man who has done his five years in the shops and been through a technical college training. It can hardly be expected that this should be otherwise; yet it would not be surprising if at no distant date women were found competing in engineering.

### Rejections

It is very necessary to arrange a proper system for dealing with rejections. When Government inspection is in force the following procedure should be adopted:—The junior Government inspector rejects. This is confirmed by a senior member of the staff, who then labels the part to show the cause of rejection, and who should also express an opinion as to whether the part can be returned to the shop for rectification. The part should then be passed back to the firm's viewers, who if they are in agreement with the Government inspector will take action accordingly; if they are not in agreement the part should be put on a "pending table" and a higher authority called in for consultation. In a large inspecting organization this is arranged for by the appointment of district and travelling officers. The main object of instituting such a procedure is that the reason for rejections may be known at the earliest possible moment to the producer, so that the cause may be removed.

## DEFECTIVE COAL CAUSES INCREASED LOSS

IN discussing the general need of fuel conservation in the boiler rooms, Van. H. Manning, Director of the Bureau of Mines, Department of the Interior, recently issued the following statement:—

There is one phase of the present coal situation which may put an entirely different light on the supposed increased production of coal of the present year. In round numbers, there was produced 600,000,000 tons of fuel last year. Statement has been made that 50,000,000 more tons will be mined this year. The preparation of this increased quantity of coal has not been as good as in times past. Analyses of samples show in many cases a greatly increased quantity of ash. Repeated cases are brought to the attention of the Bureau of Mines where coal which would run from 6 to 8 per cent. ash in normal times is running from 12 to 18 per cent. of ash in these abnormal times.

Complaint about the preparation of coal is very general and it is not at all improbable that 5 per cent. more ash is included in this year's coal than in previous years. If such a figure is true, it means that 32,500,000 tons of the estimated output of 650,000,000 tons is nothing but increased ash. If we can imagine

over 600,000 car loads of ash being added to the present burden of transportation, the evident effect on car supply and transportation troubles would be seen.

If this were the end of the matter, it would not be so bad, but there is another factor well known to engineers which is apt to be overlooked by the non-technical user. The extensive experiments carried on by the Government at the St. Louis Exposition showed that with the coals used there was a decrease of about 1½ per cent. in efficiency for each 1 per cent. addition to the ash content of the coal—that is to say, the inclusion of more ash with the coal decreases the value of the fuel not only the amount equal to the useless ash, but it makes the remaining good coal less effective to the extent of 1½ per cent. for each 1 per cent. of ash. The inclusion of 5 per cent. more ash in the fuel, therefore, means a reduction in efficiency of the remaining good coal of about 7½ per cent., which, added to the 5 per cent. useless ash, makes a total reduction in effectiveness of 12½ per cent.

According to this point of view, although 650,000,000 tons may be produced in 1917, its effectiveness as compared with previous years is probably about ⅞ of this, and equivalent to a production or normally prepared coal of about 570,000,000 tons. We have then, instead of an increased production as compared with last year, an actual decrease of effective coal of about 30,000,000 tons. If this is added to the estimated increased needs, due to our accelerated activities, of 100,000,000 tons, we have a deficiency of the equivalent of 130,000,000 tons, instead of 50,000,000 tons to make up by good engineering and true fuel conservation in the boiler room.

## HOW TO EXTRACT ANY ROOT OF ANY NUMBER

By N. G. Near.

VARIOUS ways have been published showing how to extract the fifth root, cube root, fourth root, etc., but here is a graphical method for extracting any root.

Lay off a logarithmic line AC, as long as you wish—up into the billions if desired.

Then lay a scale alongside, like BC, so that the zero of the scale coincides with the "one" of the logarithmic scale. BC may be placed at any convenient angle with AB. The instrument is now ready.

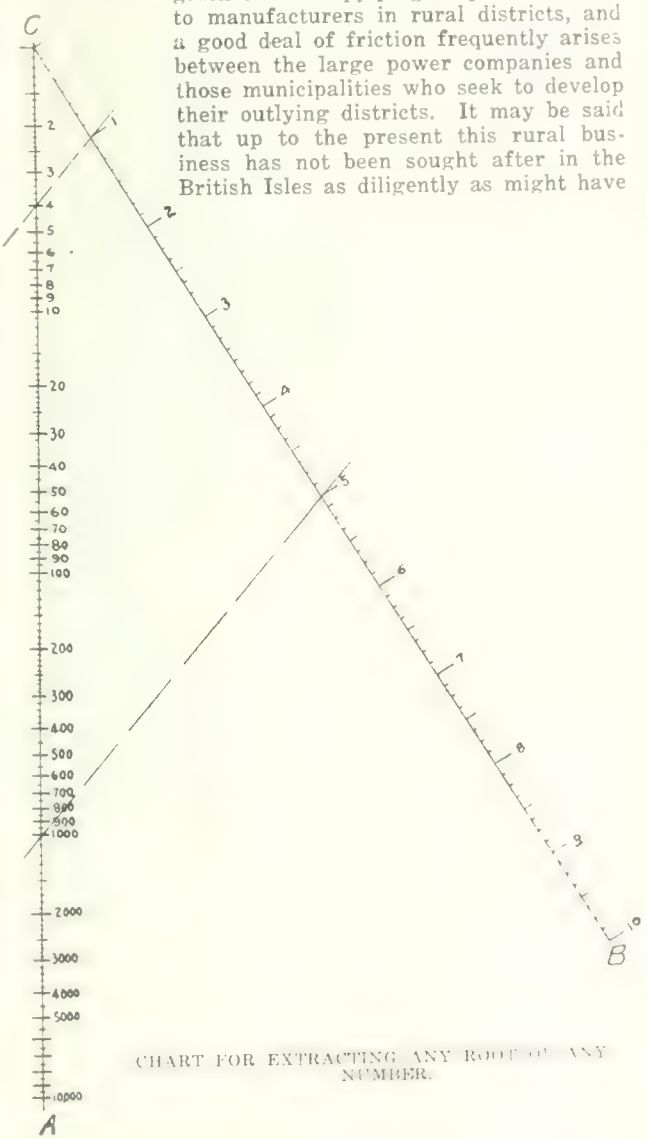


CHART FOR EXTRACTING ANY ROOT OF ANY NUMBER.

For example, what is the fifth root of 1024?

Join the 1024 and the 5 as indicated by the dotted line. Then draw a parallel line through the "1" as shown. The answer is 4. Proceed similarly for any root.

The reason why this "works" will be plain to anybody who understands the principles of logarithms, so I deem further explanation to be unnecessary.

## ELECTRIC POWER IN BULK

By L. E.

EVERY year more and more attention is given to the supplying of power in bulk to manufacturers in rural districts, and a good deal of friction frequently arises between the large power companies and those municipalities who seek to develop their outlying districts. It may be said that up to the present this rural business has not been sought after in the British Isles as diligently as might have been the case. It is perhaps due to the fact that the possibilities of its development have not been estimated at full value, or possibly the parties interested have devoted more attention to the business which is nearer home and which is more immediately remunerative.

The cost of transmission is always a serious item when the sale of power in bulk is being considered. One company has increased the distances between supports gradually until they now have solid copper conductors operating with perfect satisfaction in spans of 250 feet. How much further they can extend is now a matter for experiment, but above 250 feet it would seem that local atmospheric conditions would have an important bearing on the subject.

### Composite Conductors

Possibly copper-clad steel or other combination of metals may render it possible to increase that distance and so enable distribution to be carried out at a less cost per mile. Steel or reinforced concrete posts which are now being used in some localities may eventually do much to solve the support problem, for the simple reason that the maintenance of poles is a considerable item where the poles form a large proportion of the invested capital. Insulated copper is, of course, out of the question for rural work, as its increased weight shortens the spans, thereby raising the cost of supports, and the insulation neither adds any factor of safety nor decreases the cost of the supporting insulators.

There is some divergence of opinion as to the voltage which is best adapted for rural district supply and also as to the scheme of transformer connections which it is best to adopt as a standard. In the majority of cases 110 volts can be used for single, and 220 volts for polyphase work, as this perhaps offers the most flexibility of any scheme of secondary voltages. On the primary side may be used delta connected three wire 6,600 volts, and 2,200 volt systems.

### A Desirable Circuit

There is of course much to be said in favor of 4,000 volt or 11,000 volt, star connected, earthed neutral primary circuit for rural work, as according to A. S. Hall, who has had a great deal of experience, it has the advantage of fewer earths being necessary, thereby lowering earthing cost, and a further advantage of enabling the circuit to be cut out entirely by an automatic switch in case any of the three wires should be earthed, whereas the delta connected three wire primary will sometimes operate with one wire down. An increase of voltage is possible, with a resultant lower copper cost, and a single wire can be run to handle singe phase distribution transformers using earth return. Further, if any earth fault should develop it will be on the high-voltage side, which is the voltage being earthed against, and by earthing the secondary also the consumer is rendered doubly safe.

A plan which is sometimes followed, and which has saved considerable first cost, has been the banking of transformers in multiple, on both primary and secondary sides. This is not good practice in town work, but the objections are not so apparent in rural distribution and there is a decided saving in both transformer and copper on account of being able to use larger transformer units, and so take full advantage of the diversity factor of grouped consumers.

# PROGRESS IN NEW EQUIPMENT

There is Here Provided in Compact Form a Monthly Compendium of Shipbuilding and Marine Engineering Auxiliary Product Achievement

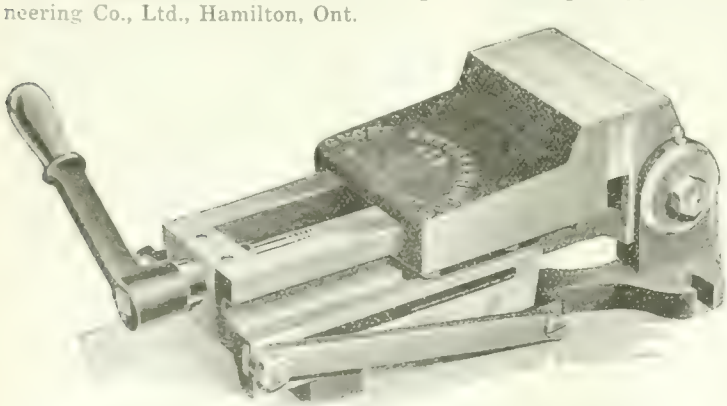
## TILTING VISE WITH GRADUATED SCALE

THE illustration shows a vise with tilting adjustment which allows it to be quickly fixed to any position from horizontal to vertical. This feature makes it applicable to a wide range of work and facilitates its use on the drill press, milling machine, shaper or bench.

It is built in two sections—the base for clamping to the work table, and the vise proper which is hinged to the base. The elevating arms are pivoted to the base at one end, while the other ends are fastened to a tee-headed bolt, working in slots on both sides of the vise. Tightening up the lock nuts on the bolts secures the vise rigidly in any position to which it is adjusted.

The jaws are 2 in. high and 6 in. wide and have a 6-in. opening. The stationary jaw is formed integral with the hinge while the movable jaw is traveled along the machined steel ways by a steel screw with buttress threads. The handle which turns the screw also serves to tighten up the lock nuts.

A machined indicator plate is secured to the hinge support and has its bevelled rim graduated in degrees. The pointer, fastened to the stationary jaw, moves over this scale and accurately indicates any angle of tilt up to 90 deg. The device is manufactured by the Globe Engineering Co., Ltd., Hamilton, Ont.



GRADUATED TILTING VISE.

## HIGH-PRECISION BALL BEARINGS

THE tendency toward higher speeds and heavier loads arising from intensified [illegible] is due to war conditions has caused [illegible]ased interest to be taken in ball-bearings capable of sustained high-speed service. The accompanying engravings, Figs. 1 and 2, show the Norma ball bearing, an open type of ball bearing made to exceptional standards of precision and instantly separable, without the use of any tools, into its several constituent [illegible] and balls. In practice, the inner and outer races are separately, independently and readily mounted—the cage with balls slipped over the inner race—and the outer race with its housing placed in position. In the manufacture of the bearing, precision measurement has been

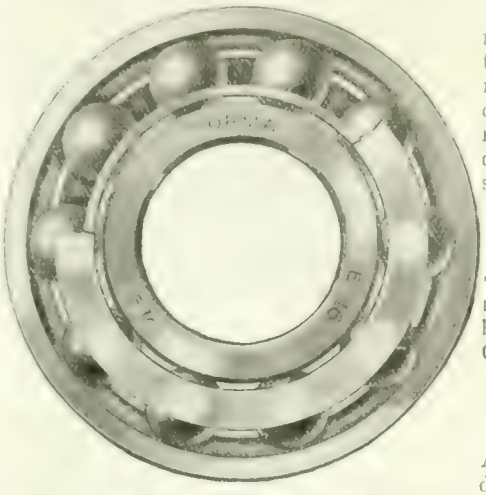


FIG. 1. VIEW OF BEARING WITH CAGE PARTIALLY REMOVED TO SHOW ARRANGEMENT OF BALLS.

carried to a high degree, the Hirth minimeter which is used on all dimensions being capable of measuring to 1-10,000th of an inch.

The open type, separable construction

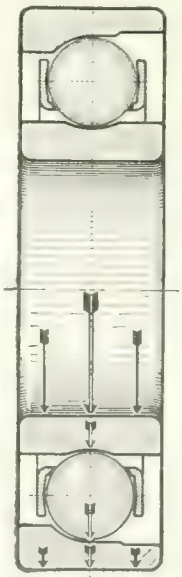

FIG. 2. CROSS SECTION SHOWING OPEN-TYPE CONSTRUCTION. ARROWS INDICATE LOAD LINES IN RADIAL LOADING.

of these bearings permits rigid mounting of both races, with its resultant contribution to speed-ability. It also facilitates assembling a machine in true alignment, thereby obviating cramped, misaligned bearings and consequent excessive wear, while the almost instant accessibility of every part of the bearing invites that frequent inspection and easy cleaning which is so essential to a maintenance of perfect operating conditions. The metals used in these bearings are made to rigid specifications and parts are specially treated to make the most of the inherent qualities of the metal.

The speed limits of these bearings are not definitely known, for the reason that tests to destruction have never been made. They are, however, used in machines where a speed of 35,000 revs. per min. is reached without any evidence of distress or failure; constant operation at speeds of 3,000 to 6,000 revs. per min. is maintained in many machines.

The suitability of this bearing for high speeds has led to its extended use in magneto and lighting generators for motor vehicles, aeroplanes, etc. These bearings are the product of the Norma Company of America, New York City.

## PLAIN RADIAL DRILL

A PLAIN radial drill with speed box drive as shown in the accompanying engraving is now being built by the Morris Machine Tool Co., Cincinnati, in 4 ft. and 4½ ft. sizes. The drill can also be arranged for cone pulley, constant speed motor in connection with speed box or variable speed motor drive.

The arm slides up and down on a column by power with safety stops in extreme positions and the column swings around a stump that runs through to the top of the column. At the top of the stump a combination annular and thrust ball bearing is mounted, which carries the entire weight of the column and arm. At the bottom of the column there is a plain bearing on the stump. This construction permits the arm to swing with ease. The stump is securely mounted on a heavy base which is deep and well ribbed. Around the edge of the base is a lubricating channel which drains to a reservoir. The base is so arranged that oil pump and piping can be attached at any time.

The lever at the bottom of the stump, standing in a vertical position, controls the friction clutches on the pulley shaft in the speed box. This lever, which is convenient to the operator, when in neutral position, stops every gear on the machine, and in connection with the double back gear lever on the head, the operator can secure six spindle speeds instantly. With the speed box, eighteen spindle speeds are available and on the cone pulley drive there are fifteen spindle speeds. The double back gear is mounted on back of the head and is fully enclosed.

Back gear clutches and clash gears are made of nickel steel heat treated and hardened. Tapping attachment mitre gears are also mounted on back of the head and are enclosed in an oil tight case and run in oil. Frictions are of the

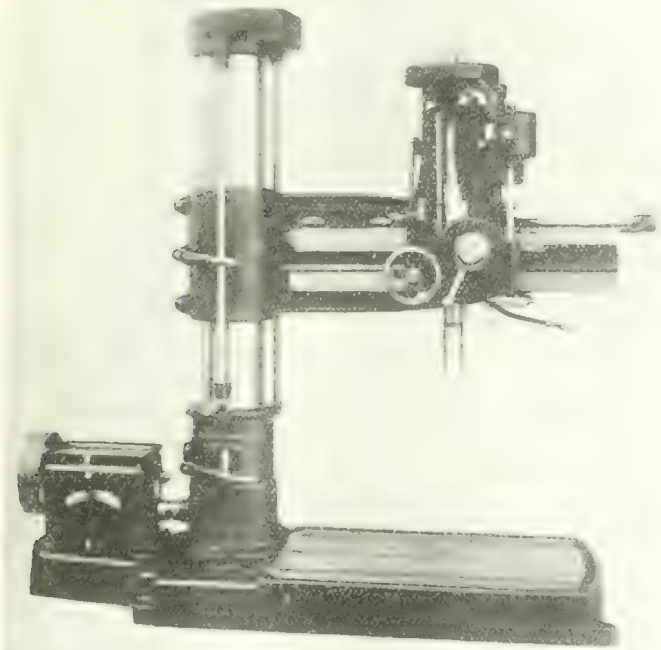
expanding ring type capable of pulling the maximum capacity of the drill and controlled from the front of the machine. Friction rings are adjustable.

The head is heavily constructed with long bearings for the spindle. It travels on the arm on wide bearings by means of a hand wheel through reduction gears to a rack and pinion.

Spindle is equipped with a ball thrust bearing. Bearings throughout are of bronze with felt wipers. A recess around the bearing acts as an oil reservoir. Through feed gear box mounted on the head, six feeds are obtainable. A direct reading depth gauge is provided, arranged to throw the feed out. A safety feed throw out is arranged at the end of the spindle travel.

All gears are of steel except the spindle gear which is semi-steel, made of one-third scrap steel mixture. Speed box is fully enclosed and gears run in heavy oil. A tool tray is mounted on top of the box. A speed plate is furnished, giving the operator all spindle speeds at certain positions of the lever.

Principal specifications of the 4 ft. drill are as follow: drills to center of 8 ft. 6 in.; maximum distance between spindle and base 60 in.; minimum distance between spindle and base 10 in.; maximum distance between spindle and table 39 in.; spindle traverse, 16 in.; spindle diameter above sleeve 1 15/16 in.; spindle—Morse Taper No. 5; spindle speeds—Cone Drive 19 to 350; spindle speeds—Speed Box Drive 20 to 350; working surface on base 36 in. x 51 in.; working surface on table 18 in. x 24 in.; weight crated—about 7,500 lbs.



PLAIN RADIAL DRILL WITH SPEED BOX DRIVE GIVING EIGHTEEN SPEEDS.

## NEW CENTRIFUGAL PUMPING PLANT AT TORONTO RIVERDALE STATION

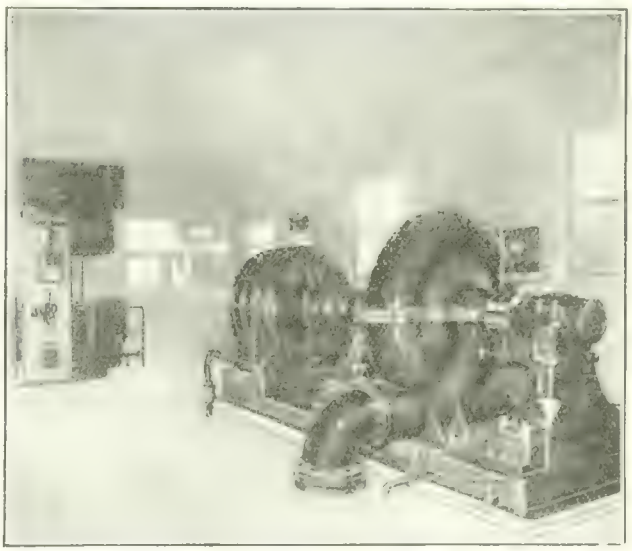
THE motor driven centrifugal pumping plant recently completed at the Riverdale Station of the Corporation of Toronto is of interest to municipal and other engineers, owing to the great flexibility of speed and capacity of the unit. It was designed to deliver five million imperial gallons in twenty-four hours against a head of 170 ft. and running at a speed of 720 revs. per min., but owing to probable variation in pressure and capacity the city required the unit to deliver either three million gallons or one million gallons against a lower head varying from 130 ft. down to 70 ft.

Under such conditions, it is usual to build a multi-stage pump but the contractors, Canadian Allis-Chalmers, Limited, designed and built a single-stage pump which has fulfilled all the guarantees required by the city. The usual practice also is to supply constant speed induction motors for centrifugal pumps; however, as the speed to fill the above requirements must vary from 720 revs. per min. down to 350 revs. per min., the Canadian General Electric Co. built a special 250 horse-power variable speed motor which also fulfills all the requirements.

The pump, which is single-stage with split casing, consists of a cast iron spiral casing with discharge and suction inlet cast on to the lower body. The casing is split on a horizontal centre line, so as to facilitate inspection without dismantling pipe or any other part of the unit. A set of removable diffusion guide vanes has been provided so as to guide the water from the impeller to the casing in the most effective manner. The impeller is made of cast bronze, and polished so as to eliminate unnecessary friction.

Special neck rings have been provided so as to decrease the water leakage from the pressure side to the suction side. The impeller is of double suction type and the head of 170 ft. is generated in a single stage. Proper stuffing boxes are arranged on each side of the extending shaft, and bronze sleeves are provided to eliminate rust and prevent undue wearing. The shaft itself is of hammered steel and of ample stiffness to prevent any vibration.

Separate outboard pedestal bearings are provided in order to carry the shaft, and one of these bearings is arranged with forged collars which act as a thrust bearing to take any unbalanced thrust which might occur occasionally. All bearings are arranged for water cooling, and are of the self-aligning ring oiling type. Separate sub-bases are provided to facilitate dismantling and direction. Both bearings are tied up to the main pump casing by means of stay bolts, so as to make the whole unit as rigid as possible. A flexible pin type coupling is arranged for connecting up this pump with the motor.



CENTRIFUGAL PUMP WITH CAPACITY OF [illegible] IMPERIAL GALLONS IN 24 HOURS.

The whole unit is set upon a heavy cast iron base-plate which is grouted in to the foundation, and has proven to be exceedingly quiet during operation. An efficiency of well over 70 per cent. has been shown operating under various conditions.

The Eagle and Globe Steel Co. [illegible] treal, has been absorbed by the Arthur Balfour & Co., and in future all Canadian business will be carried on under the name of Arthur Balfour & Co. Apart from the change of name no alterations will be made in the Canadian offices, W. A. Bradbury continuing as general Canadian agent.

Vol. XIX. JANUARY 3, 1918 No. 1

## WHAT BRINGETH THE YEAR?

ON very few occasions in the memory of those living has the beginning of a new year been so fraught with possibilities, beneficial or dire, probable or improbable, as the beginning of 1918. Week after week, month after month, year after year the war has been influencing our lives to an extent not yet comprehended by all of us though more or less fully comprehended by some.

Many, very many, have been bereaved, too many have suffered and died, others have toiled beyond preconceived measure and the end is not yet.

Even as the year is born we are witnesses of the most impressive contrast ever afforded in the history of nations in our ken. The most threatening combination of militaristic powers ever centred in the grasp of a few ambitious madmen is making desperate efforts to call it quits and assume the role of peace-loving brethren of mankind, while the most peaceable of the world's leading nations is just as desperately straining every nerve and fibre to prevent the perpetration of the most gigantic fraud on civilization ever attempted.

Despite the delirious camouflage being indulged in by the Huns, the United States makes ready for the final bout with undeviating aim and an intensity of purpose, the effects of which are reflected in the foe's desire for peace.

**"Achievement of the purposes for which the Allies are fighting is essential to the future freedom and peace of mankind."**

This score of words forms part of a letter sent by Premier Lloyd George to the special National Labor Conference held at Westminster, Dec. 28, which had been convened to consider a memorandum on war aims. The conference was attended by 750 delegates and went on record by a virtually unanimous vote that Labor, in continuing the war, is actuated by a determination to make the world safe for democracy hereafter.

In reaching such a decision, Labor has demonstrated that it has risen to the occasion like other essential components of civilization. During the few years immediately preceding the war the claim was made that war would never be possible on a decisive scale as the workingmen of the various countries would never rise in arms against each other, or in any way allow their services to be utilized in carrying on hostilities. Had such a scheme been feasible and strictly adhered to, and the calculated results obtained, the war would not only have been short-lived or never started, but the progress of the world toward democracy would have been immeasurably advanced.

The manner in which developments actually took place is now history. When the time for a decision came, the Huns unmasked themselves, their previous regard for the brotherhood of man was seen to have been but a feint to lull vital sections of the Allies' forces into a reluctant attitude which might have had very serious, albeit not deliberate, influences on the course of hostilities, and allied Labor was left with the alternative of admitting the failure of its previous ideals or being guilty of culpable slacking.

The results of the Conference, while definitely negativing any suggestion of guilt, are of special significance in view of conditions in Russia. Untrammeled liberty is more dangerous to a nation's welfare than untrammeled power. Reports from reliable sources indicate the gradual merging into chaos of many elements whose former efficiency elicited unbounded admiration from those who had opportunities to judge.

Freedom unbounded, uncontrolled, aimless and selfish—such a state induces national disintegration at an appalling rate. Freedom—unbounded but controlled, realization of its worth stimulating every effort for its defence, unselfish sacrifice a feature of its devotees—such an ideal is the inspiration of the great marshalling of finance, commercé and industry which we, as neighbors of the United States, are privileged to witness at close range. It is not what the name itself is, as what it stands for that counts to-day. Freedom, like the rose, by any other name would be just as sweet.

**"The ideals for which we are fighting to-day are precisely those for which the British Empire entered the war."**

In assuming the burdens of the coming year, burdens which will grow heavier and yield less recompense, we must keep graven on our mind this further statement by Britain's premier. The longer we have fought for them the more will we value our ideals when they are finally won. And, in this, the critical and possibly final year of the struggle, let it be ours to so act that of none of us can it be said "he eased off his hold."

"The last man and the last dollar" is an extreme figure of speech, but it can become an unwelcome reality through unscrupulous manufacturers advancing unfounded exemption claims and extracting undue profits for their personal gain—in which case the effects on the efforts of the country are exactly opposite to those originally intended by the speaker of these words.

With the official declaration of British Labor referred to, the reputation of Labor as a stable element of the Empire remains unsullied; with the advent of government control of railroads in the States the singleness of purpose of the Republic is made still more manifest; for Canada, a continuance of past efforts will more than maintain the good name of the Dominion as a tower of strength in time of stress.

The future will soon be with us. Let us see that it finds us ready for all that it may bring.

# WANTED—
# HUNDRED POINT MEN

By
GEORGE A. SIMPSON

ALL over this great Continent, geographically known as the United States of America and Canada, there are to-day many prosperous industries which were, a few short years ago, facing serious financial embarrassment and failure. ¶ These industries in many instances had been grossly mismanaged, while in others, lack of capital and kindred ills contributed to their condition; but it matters not now what was the cause; it is Results and not explanations we are interested in, as results count and the facts are, these conditions did exist. ¶ Then came the War, and as if by magic all was changed; from Adversity to Prosperity was a short shift and even Industries that were wavering on the ragged edge of failure took on a new lease of life and assumed a prosperous air. The stupendous demand for products of every description was, and is, such that extension of plant and increased production became the order of the day and under these unprecedented conditions, business to-day is pushing the man who, under normal conditions, could not push business. ¶ The whole structure---Agricultural, Industrial, Commercial and Economic---has been undergoing the most drastic change the World has ever known. But how about the man? And how about business, with its increased facilities for production and its corresponding overhead expense, when this demand ceases and Competition sets in? ¶ 'Tis said the leopard changeth not his spots, and this, in a measure, applies to business management. The test of fitness will come when the Commercial War begins and a new order of things exists, to which we must adjust ourselves. A tremendous momentum has been started and maintained on business we did not seek, and the Wheels of Industry have been greased with prices exceeding our wildest dreams. We have been floated into position, on a tidal wave of business, far and above the jagged rocks of competition, which await us when the tide recedes. What then?--- is a question worthy of sincere consideration NOW. ¶ To successfully cope with the new conditions and maintain our progress will create a demand for Hundred Point Men. Men who are well balanced--- men who are not one-sided in their development, whose energies do not seep into narrow channels, while the main streams of ability are allowed to run dry--- men who are broad, who do not take half views of things--- men whose education has been received in the school of hard knocks, whose capital is Knowledge acquired through experience, who mix common sense with theory and do not permit the technical to distort their practical viewpoint of everyday life--- men who have studied men and mastered conditions, whose love of humanity knows no bounds, who despise pretence and worship a good name--- men who can decide and whose decisions are intelligent and just, who see education and development, discipline and character in their occupation--- men who can co-operate more successfully than they can compete--- men who can honorably and persistently produce results--- such men as these are the Executives of the future--- HUNDRED POINT MEN

# Iron and Steel Price Revision Postponed

*United States Government Decides to Continue Prevailing Schedule—Severe Weather and Fuel Shortage Affects Transportation and Production Markets are Quiet Generally*

BUSINESS continues quiet which is the usual state of affairs at this time of the year. Most firms are busy stock-taking and are out of the market in the meantime. The severe weather has revealed a shortage of coal in many districts and the outlook is serious in some parts. It is not unlikely that a number of factories will have to either close down or restrict operations. The cold weather is also interfering with operations at the steel mills. Railways are also suffering on this account and the movement of freight is being interfered with, curtailing deliveries of fuel. There is no improvement in the coke situation and more furnaces have been banked in the United States which is curtailing the production of pig-iron and steel. The outlook in this respect is becoming serious. There will be no revision in prices of iron and steel in the States, it having been decided to extend the prevailing schedule. This relieves the steel market of an element of uncertainty. The iron and steel market has been quiet all the week with consumers for the most part holding off. The shortage of steel for ordinary commercial purposes continues and there is no relief in sight. Prices of non-ferrous metals are unchanged and demand has been light. The markets generally are featureless and seasonably quiet. The scrap metal market is also dull.

MONTREAL, Que., Dec. 29, 1917. —The opening of the New Year finds us on the verge of another industrial epoch, as exemplified in the recent action of both the American and Canadian Governments with respect to their attitude towards the railroads of the respective countries. The former have virtually taken over the entire control of every transportation company with a view to the more rapid movement of freight to and from its destination. The actual operation of the various companies will, however, remain under their present officials. Almost as if the movement had been pre-arranged, the Canadian Government has also taken steps to relieve the pressure that exists as shown by the granting of increased rates on the various railroads throughout the Dominion. While no stated date has been set for the inauguration of the new schedule it is anticipated that it will go into effect very early in the New Year.

### Pig Iron

The generally acute situation has been further emphasized during the past week owing to the increased difficulty of obtaining delivery of all classes of raw materials. Furnaces have been struggling to maintain operations but in many instances curtailment has been necessary in order to conserve the supplies on hand. This falling off in output, though slight, has had a serious effect on metal-working industries generally. Better conditions, however, are in sight, as the recent attitude of the Governments respecting railroad operation seems to indicate. Quotations for Canadian pig ore nominally $50 per ton, but [illegible] is available.

### Steel

[illegible] production of iron and steel of every description has been somewhat curtailed owing to the holiday season and the general disorganization contingent to the Federal Elections. These disturbing elements, [illegible] activity either in manufacture or transportation. Recent developments in the railway situation promise relief, but it is a little early to predict what will result from this most recent step. The shortage of coal has become very acute and it has been found necessary to close many factories and public buildings in order to conserve the available supply. The new regulations governing railroad operation will, it is hoped, enable officials to give a much better service in respect to the delivery of coal and other essential materials for manufacturing and general industrial purposes.

Canadian conditions are much the same as last week, the excitement of the elections and the festive season not yet being entirely dispelled. With the opening of the New Year it is expected that impetus will be given to industrial activities, as further appropriations from the recent loan are looked for, and the congestion of the past few weeks may be relieved by the new developments regarding railroad operation. Increased requests for shipment has been a result of the pending advance in rates, so as to take advantage of the old rates while they are still in force. Local steel prices are unchanged on a strong but quiet market.

### Metals

The metal situation is much the same and conditions are still dependent on developments at the American capital. Little interest is shown by buyers as they are reluctant to purchase heavily under the uncertain conditions. Copper is quiet but firm at fixed prices. Tin is easier following the drop on the London market. Spelter is firmer but uncertain. Visible lead is apparently scarce and a stronger tone is evident. Antimony and aluminum are quiet and unchanged.

**Copper.**—Consumers are being well taken care of at present and the supply appears to be sufficient to meet all the requirements for essential manufacture. Local dealers report a quiet but steady market with quotations unchanged at 23 and 32 cents per lb.

**Tin.**—Trade conditions appear to have shaken off some of tension that has characterized this market for the past several weeks, but the acute situation is still more or less pronounced. New regulations imposed by the British Government and the recent decline on the London market have been reflected in the easier tone of the New York market. Lack of further detailed information regarding the recent action of the British authorities has, however, placed the American trade on its guard respecting buying of future supplies, and until the permit question is cleared up the market here will continue to be more or less unsettled. Spot tin is still practically impossible. No quotations are given in New York, while dealers here are asking 77 cents, a decline of one cent on the week.

**Spelter.**—The situation in spelter has developed a little firmer tone but is still very irregular. The market is rather disturbed over the report that production has been curtailed, this being partly through the desire of the smelters but largely from the inability to secure delivery of coal for operating purposes. The strength of the market is shown in the slight advance quoted on the New York market and the expectation that further business will be placed for Government requirements. The position of spelter on the local market is firmer but prices are maintained at the previous quotation of 10½ cents per lb.

**Lead.**—The difficulty that has been experienced in the delivery of coal and other materials has resulted in the curtailment of production and in consequence the tone of the lead market has become stronger. The American Government is endeavoring to maintain a stable market and it is very unlikely that conditions in the coming year will duplicate those of the past twelve months. The market here is developing a little more activity. Prices are firm but unchanged, dealers asking 9½ cents per lb.

**Antimony.**—Uncertainty is the dominating feature in the present market owing to the doubt that appears to exist as to the actual war requirements of the American Government. This has had the tendency to maintain the market in

a firm position but a certain feeling of nervousness is everywhere apparent. The situation here is unchanged with prices holding steady at 18 cents per lb.

**Aluminum.**—The market is quiet and unchanged with quotations firm at 60 cents per lb.

### Machine Tools and Supplies

In common with all other activities the machine tool industry has felt the effect that has followed the recent elections and the present holiday season, both these factors tending to disorganize the ordinary trend of industrial life. No developments of importance have taken place to create renewed interest in this particular line of manufacture, but it is expected that a little impetus will follow the turn of the New Year when the resumption of business again falls into its usual groove. Very little activity is reported in connection with munitions machinery, although the inquiries for general equipment continue to be of fair volume. General supplies are still in fair demand owing to the steady activity in industrial circles. Prices on all commodities are well maintained.

### Scrap

The old metal market has suffered more or less during the past week from the cold weather that has prevailed, this preventing the free movement of material on the different railroads. Business this week has been quiet but prices have been well maintained, the quotations here being practically the same as last week.

## Toronto

TORONTO, Ont., Dec. 31.—The close of another year finds the industrial situation in Canada on the whole very satisfactory. Orders are plentiful, but supplies of raw materials are high in price and scarce in some cases. This latter feature is tending to restrict production and the volume of trade is not as heavy as it would otherwise be. The scarcity of skilled labor has also handicapped manufacturers and it is likely that the situation in this respect will become worse owing to the selective draft. The severe weather has revealed a serious shortage of coal in many parts of this province causing considerable suffering and curtailing manufacturing operations. The severe cold has also practically cut off supplies of natural gas in some parts, principally in Western Ontario.

### Steel

Quiet conditions prevail in the steel market, which is usual at this time of the year and there is practically no change in the situation from last week. The demand for steel for commercial purposes continues light on account of the general slowing down of manufacturing activity due largely to the difficulty that is being experienced in obtaining steel, particularly from the United States. The outlook for consumers of steel for commercial purposes is not very bright for the coming year and it is likely that the output of a number of finished products will be considerably curtailed. Manufacturing operations cannot help but be restricted owing to shortage of raw materials on account of the heavy and increasing demand for steel for war equipment. Plants engaged upon government work are in a class by themselves and are not suffering the same inconveniences that other plants are subject to. So many plants, however, of one kind or another are engaged upon government work that the apparent quietness in the market does not affect the situation to the same extent as in normal times. In other words, although the outside market is dull there is a continuance of activity among industries engaged upon the production of munitions and other war supplies. The mills are busy and have more orders on hand than they can readily take care of, a large proportion of the business being government work in one form or another. The severe weather will interfere with mill operations and restrict the output to some extent while it will also hinder the transportation of raw materials affecting principally those mills whose source of supply is in the United States.

The situation in regard to prices has been cleared up by an anouncement that the present schedule will be extended for a certain period, probably three months. The War Industries Board, Washington, has recommended an indefinite extension of the price schedule fixed last September. It is expected that President Wilson will in the near future issue a proclamation extending the present schedule. Further recommendations have been made regarding fixed prices on a number of miscellaneous iron and steel products. The new list covers steel castings, railroad fastenings and track supplies, including spikes, angle bars, tie plates, etc., cut nails, and forging ingots. Some of these prices are as follows. Forging ingots at $73 per ton, splice bars and tie-plates at 3.25c per pound, rail 3.90c, iron spikes at 4.50c, track bolts at 4.90c and cut nails at $4 per keg, also fixing schedule on steel castings and cast iron pipe. Some of the above products had been gradually adjusting themselves to the new market basis, so that the formal announcement means no abrupt change.

**CANADIAN GOVERNMENT PURCHASING COMMISSION**

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

### Pig Iron

There is no improvement in the pig iron market, in fact the situation has become more acute owing to the severe weather interfering with the movement of freight. In the United States the shortage of coke and fuel has become more acute and has further handicapped the production of pig iron and likewise steel. Now that the American Government has taken over all the railways there will doubtless be some improvement in the transportation situation, although it will take some little time before relief measures can become really effective. More furnaces have been banked and production has thus declined. There is no iron for nearby delivery and all reserve stocks have been exhausted. Fuel Administrator Garfield announced a few days ago that there would be no general revision of coke prices for the year 1918.

### Scrap

The scrap market is stagnant and featureless. The fixing of prices in the United States of heavy melting scrap will make the market more settled here.

### Machine Tools

The market has been quiet all the week on account of the holiday season, but a revival of activity will likely develop after the new year.

### Supplies

The market is seasonably quiet this week with prices generally holding firm. Cut nails, however, have declined 15c per 100 lbs., which makes the base price $5.65 per 100 lbs. An advance in lubricating oils is looked for principally on account of the increase in cost of tins and containers.

### Metals

There is very little of importance to note in the metal markets this week and there have been no price changes. The situation remains the same as last week with business dull, which is usual at this season of the year. The copper market is quiet with very little interest being shown by consumers. The tin situation is unchanged and continues acute on account of the scarcity of metal. Spelter is firmer due to large purchases by the United States Government. Lead is quiet and demand light, although prices are firm. Antimony and aluminum are both quiet at unchanged prices.

Copper.— routine affair and quite devoid of excitement. This is due to the fact that consumers are assured as to supply and of a uniform price. Spot copper, however, can only be had in small lots as distributed by jobbers. Lake and electrolytic are quoted at 32c and castings at 31c per pound.

Tin.— and the acute shortage continues. Shipments are arriving from time to time, but are already sold into consumption long before arrival. Inquiry continues heavy, but in the absence of offerings trading is light and prices nominal. Local prices 80c per pound.

Spelter.—The U. S. Government recently purchased a considerable quantity of grade C spelter, which has stiffened the market, although local prices continue unchanged at 10½c per pound.

Lead.— of the quiet market and absence of demand. There is enough lead produced and in process of production to provide for all natural requirements and leave a sufficient surplus for private consumption

so that exceptional prices should not prevail. Local quotations 8½c per pound.

**Antimony.**—There is no change in the situation. The demand is quiet and price steady at 18c per pound.

**Aluminum.**—The market is quiet and quotations unchanged at 62c per pound.

## Washington

WASHINGTON, D.C., Dec. 28. The United States made its second great step in the war game at noon to-day, when all railroads passed under Government control. With conscription as its first great war move, the United States has now taken the second step in taking over the activities of the railroads. The importance of this action in respect to the progress of the United States' war programme is great. William G. McAdoo, Secretary of the Treasury, as predicted by your correspondent last week, is the railroad dictator. McAdoo has already taken long steps to bring about a remedy to the railroad congestion which has been hampering the United States for many months. All traffic and facilities of railroads are to be pooled, according to orders issued by McAdoo. This will allow one railroad to use the terminal facilities and equipment of another, and will mean that the thousands of miles of railroads in the United States will act as a unit.

With this step taken by President Wilson, there now appears on the horizon a solution for many of the problems which have been the subject of worry on the part of United States officials. The first of these is the transportation of troops.

**Better Freight Movement Anticipated**

Perhaps an even greater effect which will be brought about will be the fast movement of freight. For many weeks now freight of all sorts has been congested on railroads in the United States in a hopeless tie-up. McAdoo is to-day using his wide powers to move all of this material. Munition factories and other war material making plants which have been tied up for lack of material may now go ahead at top speed.

Canadian manufacturers will benefit largely from this action, because those supplies which Canadian manufacturers depend upon the United States for have been caught in the great freight jam. These supplies will now move with rapidity.

Railroad stocks have advanced from ten to twenty points on all markets following the action of President Wilson. This move has been a great boon to all holders of railroad securities throughout the nation and has given the stock market greater impetus than any single act since the outbreak of the war. More than a million and a half shares of stocks were sold on the New York exchange following the announcement.

**Government Control to Solve Coal Shortage**

In the Government control of the railroads [illegible] for the coal shortage in the United States. Fuel Administrator Dr. Harry A. Garfield told the Senate Investigating Committee that the coal supply of the United States has been reduced by 20,000,000 of tons because of the car shortage. W. B. Colver, Federal Trade Commissioner, declared that the entire shortage of 50,000,000 tons in the United States was caused by a lack of transportation facilities. The sub-committee of the Senate investigating the coal shortage is satisfied that the railroad control will relieve the coal shortage, and has, therefore, directed its attention to the prices of coal. In this respect again Canadian manufacturers will profit. Movement of coal to Canadian points promises to be more steady, and if Senators are able to put through legislation which they now have in mind there will be a downward revision of coal prices.

**Government Control of Coal Mines**

Government control of coal mines is expected to be the next step of the United States Government. Already Fuel Administrator Garfield has warned coal operators that all of their contracts must be made subject to requisition of the United States Government and no contracts may be made for a period longer than one year. Dr. Garfield has served notice that he will ultimately take over the control of all mines. "It is not a question of when, but how soon," he has said.

**The Shipbuilding Situation**

The United States Shipping Board, goaded on by Congressional investigation, is now speeding up to a considerable degree. Henry Ford, automobile manufacturer, has been sent to the Southern States to lay the foundations for plans for a series of great shipyards to be constructed at once. Congressional investigation of the Shipping Board has developed the fact that the delay in shipbuilding has been partly due to transportation difficulties, and this obstacle will also be removed by the Government control of the railroads. The wooden ship programme has been a flat failure, according to the statement of Admiral Bowles, naval constructor, and it has hindered the American shipbuilding programme. Hence it now seems to be doomed to oblivion.

American industry has taken a great spurt in the past few days under the promise of Government regulation of railroads and war work in the United States is now speeding on with greater determination than ever before.

## New York

NEW YORK, Dec. 28.—Shipbuilders, war munition manufacturers and the United States Government are still actively in the market for machine tools. It is estimated that contracts placed in the past week and the new contracts pending will call for the early expenditure of $3,000,000. The fact that the Ordnance Department of the Army is still trying to place large contracts for guns is taken as an indication that further large orders for machine tools will come before the manufacturers early next year.

The Foundation Co. has come into the market for machinery to be installed at plate and angle shops at its local ship plant, through the Liberty Steel Products Co.; the list of tools is a large one. The Southern Shipbuilding Co. is about to enter the market for equipment for its new plant at Charlestown, South Carolina, and the Chickasaw Shipbuilding Co., the Southern shipbuilding subsidiary of the United States Steel Corporation, is preparing a list of tools for its Mobile, Ala. plant. The Kettler-Elliott Co. of Chicago, controlling the new Pensacola Shipbuilding Co., has placed a contract for 30,000 tons of steel plates and shapes with the American Bridge Co. required for the construction of ten 9,400 ton cargo boats for the Emergency Fleet Corp. Ten shipways are to be constructed at Pensacola, mainly of wood. The buildings also are to be largely of wood. Shop equipment will probably be placed in the New York market. The steel for the ships will not be required until early in June.

A large munition plant is to be built at Cincinnati, soon after the first of the year, by the co-operation of a number of prominent manufacturers of machinery who will be in a position to equip their own plant. The General Motors Corp., which recently received a contract for 5,000 Liberty motors has distributed the work among the Cadillac, Buick, the Northway, and the Chevrolet works. The Detroit Shell Co., recently organized with a capital of $2,000,000, has already received a $30,000,000 contract for projectiles and it is understood that an additional contract up to $100,000,000 will be placed with this concern. The equipment of the new plant will require the purchase of a very large number of tools.

The recent contract for howitzer gun mounts placed with the Standard Steel Car Co. calls for the expenditure of $60,000,000 by the Government and a large list of tools required for this work is now before Eastern machinery manufacturers. The Harroun Motor Co., Detroit, has received a large contract for 6-inch shells. The S. A. Woods Machine Co. of Boston has purchased 40 lathes and other machine tools to be used in the manufacture of trench mortar bombs. The American Steam Gauge & Valve Co., Boston, and the International Arms & Fuze Co., Bloomfield, N.J., have taken Government contracts for detonators. The Amesbury Brass & Foundry Co., and the Howard & Bullough American Machine Co. Ltd. have also received Government orders for war munitions including guns and shell mounts.

The taking over of the railroads by the United States Government will probably expedite the placing of contracts for cars and motive power for domestic roads. Although the car builders booked orders in 1917 for nearly 120,000 cars, less than 52,000 were for home roads, these being the smallest contracts placed for cars in twenty years while the needs of transportation companies were never so great. The United States Government, however, ordered 22,775 cars for the railroad in France con-

structed for the use of the United States expeditionary forces. Contracts were also placed for 61,775 cars for foreign countries, exclusive of the 30,000 for Russia, which contract has been suspended. The building of these cars has called for 1,200,000 tons of steel, but the car manufacturers state that they are receiving only 40 per cent. to 50 per cent. of their steel requirements. The locomotive builders received orders during the year for 5,672 engines the building of which call for 1,135,000 tons of steel.

## Pittsburgh

PITTSBURGH, Pa., Dec. 29.—Unless the unexpected occurs, there will be no revision in iron and steel prices at this time or in the near future. After a conference with the Federal Trade Commission, the War Industries Board has recommended to the President that no change be made at this time, and a proclamation to that effect will probably be issued, perhaps formally continuing present prices until April 1.

Undoubtedly there is room for a reduction in prices with regard to the great bulk of the production, but some manufacturers, peculiarly positioned as to raw materials or otherwise, might be unable to produce at a profit in the event of a great reduction. Apart from this fact, the working of the set price system depends upon the voluntary cooperation of manufacturers, and this might not be so easy to secure if the manufacturers felt they were unjustly treated. As a practical matter the lapse of time sees the working out of old contracts at higher than the set prices, and without their being replaced to the full extent by fresh sales. Thus, apart from Government orders the producers will find themselves from month to month with less commercial business on books and reductions in the set prices might occur later in a smoother manner, while there is the possibility of traffic conditions on the railroads so improving as to permit full production of pig iron and steel, and in that event there would be a much better supply of material. Finally, there is the possibility of the Pomerene Bill being passed by Congress to furnish legal authority for the fixing of iron and steel prices. Thus, the fact that it seems quite undesirable to undertake to reduce iron and steel prices at this time does not mean that there will not be reductions later on, possibly only a few months hence.

### Railroad Pool

The iron and steel industry is well pleased at the decision reached by President Wilson to take over the operation of the railroads, as announced in the proclamation of December 26. It is felt that this arrangement has no drawbacks and many advantages. While the General Operating Committee, conducting the pool of railroad facilities ordered a month ago by the Railroads' War Board, has accomplished some good, it has been constantly hampered by the anti-pooling laws, and these, of course, are to be sus-

## Enlarged Canadian Trade Intelligence Service

Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.

CHILE—Valparaiso, British Consul General.

COLOMBIA—Bogota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General, Petrograd, British Consul General, Vladivostock, British Consul General, Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Para, British Consul. Rio de Janeiro, British Consul General.

## Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 16, Buenos Aires, Canadian Commercial Commission.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Canadian Commission.

CHINA—J. W. Ross, 1 Nanking Road, Shanghai, Canadian Commission.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. M. Cornell, H. M. Consular Office.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgoiza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—[illegible] address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

the roads will doubtless result in the rescinding of the priority orders, the Government [illegible] a traffic manager to direct the movement of Government material. While the priority orders are blind, the traffic manager will be an individual with a brain. The steel trade also has its own interest in the Governmental taking over of the railroads, in that it doubtless means eventually the placing of orders for cars and locomotives to be financed by the Government.

### Traffic Conditions

Supplies of coke for the blast furnaces and of coal for the steel mills have not improved in the past week. The merchant furnaces tributary to the Connellsville coke region are producing pig iron at about 80 per cent. of capacity, while the steel interests are operating their blast furnaces at an average of 70 to 75 per cent. of capacity. The Carnegie Steel Company shows the lowest rate of operation of any of the large interests, and as it has coke production of its own, the circumstance suggests that the restriction is due to an insufficiency of transportation. Operations at steel works are cut down by the shortage of pig iron, as there have been no reserve stocks of pig iron for months. In some cases there is additional restriction by reason of insufficient coal supplies. Thus the Republic Iron & Steel Company has its blast furnace operations only slightly restricted, while its entire Bessemer steel making and rolling department has been down for nearly three weeks on account of there not being enough coal. The open-hearth department is kept in operation, as that is where the Government orders are.

### More Set Prices

The American Iron and Steel Institute has issued a long statement, setting additional prices, the most important of which are: Angle splice bars, 3.25c; single shoulder tie plates, 3.25c; standard railroad spikes, 3.90c, these base prices being subject to the usual trade extras. A long list of prices and extras is given for steel castings.

While manufacturers nearly all assert that the system of set prices is working very well, and some buyers have the [illegible] that there is no complaint. There is considerable complaint in some quarters, but referring to the manufactures of steel more than to the ordinary rolled products of the mills. It is asserted that some of the manufacturers are openly quoting prices higher than those set, and that some have even tried to impose upon the [illegible] maintain that the set prices are minimum prices, not maximum. There is complaint, too, that producers have not adjusted contracts to the set prices when [illegible]

### Pig Iron

With production of the merchant furnaces in Western Pennsylvania and the valleys and along the lake front curtailed by about 20 per cent. the make is naturally not sufficient to meet requirements of existing contracts, and there is no iron offered for sale in the open market, as has been more or less the case for weeks past. There is very little inquiry from foundries, as they are receiving moderate shipments and the operations of many of them are curtailed, particularly those making sanitary ware. It is asserted in some quarters that the steel works, by reason of their own production being curtailed, would buy large tonnages of Bessemer and basic iron if the iron were obtainable, but one should not be so sure about this, as the works may feel that in time they will be able to fill their orders with their own pig iron at correspondingly lower cost, and they cannot be certain of replacing the orders in full with other orders at high prices.

The finished steel market has continued practically stagnant. There is scarcely any inquiry from ordinary commercial buyers, while offerings are correspondingly limited. The condition is not necessarily a criterion of the relation between supply and demand, because at this time of year buyers are never actively in the market, while on the other hand producers would have no incentive to offer material in this market. A few weeks later there may be a clearer line on actual market conditions, particularly if railroad conditions are so improved as to result in heavier production of pig iron and steel.

## U. S. REQUISITIONS ELECTRIC POWER

TO assure the adequate supply of electric power for establishments engaged in war work at Niagara Falls and Buffaolo, the United States Government last Friday requisitioned the electric power produced, imported and distributed by the Niagara Falls Power Co., the Hydraulic Power Co. of Niagara Falls, and the Cliff Electrical Distributing Co.

Canadian demands that approximately 100,000 horsepower of current imported from the Canadian side should be applied exclusively to war work were said to have been a determining factor in the Government's decision to requisition all power.

Operation of mills is not expected to be affected materially by the new order, as readjustment of the power supply had been effected previously by representatives of the War Industries Board conferring with the Buffalo manufacturers.

Approximately, 110 factories not working directly on war contracts will curtail their electric power requirements somewhat, will use power at times when munitions factories are making their smallest demand, and will substitute steam for electricity as much as possible.

## PLANS FOR REBUILDING HALIFAX

A REPORT has been submitted by Thomas Adams, town planning expert of the Conservation Commission, to the Board of Control at Halifax, N.S., regarding the reconstruction of the devastated area in that city. The report went into considerable details showing the magnitude of the problem with which Halifax is confronted. After some discussion the Board decided to request Premier Murray to call representatives of the City Council, the Board of Trade, the Provincial Government, the Federal Government, the Executive of the Relief Committee, the Town Planning Board and the naval and military authorities, with a view to having a permanent commission appointed to deal with all matters pertaining to the rebuilding of the destroyed portion of the city, and with all problems which are the outcome of the recent disaster.

## NEW OVERSEAS TRADE DEPARTMENT

SIR ARTHUR STEEL MAITLAND, who has been appointed head of the new Overseas Trade Department, outlined to representaticves of the press recently its organization and projected scope. Describing the new office as a joint department of the Board of Trade and the Foreign Office—a *mariage de convenance* is perhaps the aptest phrase—Sir Arthur went on to sketch its composition. It is to take in the following old departments: (1) The Department of Commercial Intelligence of the Board of Trade. (2) The War Trade Intelligence Department of the Foreign Office. (3) The Foreign Trade Department of the Foreign Office. (4) The Consular Service and the Consular Department of the Foreign Office. This last service will not be definitely handed over to the new department until it has obtained offices adjoining the Foreign Office, but in the meantime its affairs are placed under Sir Arthur Steel Maitland personally.

The new department is to have two main divisons: (1) An overseas division, separated geographically into sub-sections; (2) an United Kingdom division, sub-divided according to trade and industry.

Sir Arthur made it clear that the Department is not only to collect information, but to take action in trade matters. Its power of action is subject to two reservations. When a piece of business becomes predominantly political, it is to be handed over to the Foreign Office, and when special subjects, such as commercial treaties, arise, they are to be put in charge of the appropriate department of the Board of Trade.

An Advisory Committee is being formed representing finance, banking, merchants, manufacturers, Chambers of Commerce, and labor, and this committee Sir Arthur intends to treat as an active "Board of Directors," whose lively assistance would be asked in tackling new problems and formulating proposals.

**First Train Over Quebec Bridge.**—It is officially announced that the first passenger train to cross the Quebec Bridge will be the I. C. R. local train from Quebec to Montreal, leaving Quebec Jan. 6th.

# SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

### PIG IRON

| | |

## METAL PRODUCTION IN CANADA IN 1917

THE Department of Mines estimates the production of metals from Canadian ores in 1917 as follows: Gold, 17,000,000 ounces; silver, 23,500,000 ounces; copper, 113,000,000 pounds; nickel, 84,800,000 pounds; lead, 56,700,000 pounds; zinc, 31,000,000. The production of pig iron was about 1,186,000 short tons, and steel ingots and direct steel castings 1,735,000 short tons. The production of coal was about 14,100,000 short tons. The production of gold, silver, copper and coal was less than in 1916. The production of nickel, lead, zinc, pig iron and steel was greater than during the previous year.

Higher prices received for silver, coal and other products considerably enhanced the total value of the mineral production. It is estimated to have been not less than $200,000,000, as compared with $177,201,534 in 1916.

## U. S. SHIPPING BOARD ESTIMATED OUTPUT

FIVE million deadweight tons is the United States Shipping Board's estimate of America's 1918 output of shipping based on builders' reports that show the Government's programme of 8,246,308 tons is 18.2 per cent. on its way to completion.

The forecast is a minimum estimate with one labor shift figured. Every effort will be made to put on two, and wherever possible three shifts in yards throughout the country. With the task of designing models, the problem, according to Shipping Board officials, is that of obtaining labor and materials.

The reports disclose that the wooden programme is 9 per cent. under way, the requisitioned steel ships 39 per cent., and the contract steel ships 4 per cent. on their way to completion.

## LUMBER TRADE PROSPERING IN BRITISH COLUMBIA

GENERALLY speaking, the lumber mills of the Province of British Columbia have had a good year, although increasing supply costs and the shortage of labor have given the lumbermen cause for worry. In 1916 the Government figure for the total lumber cut of the province was 1,280,000,000 feet. In 1917 lumbermen say they would not be surprised to see the total cut approach the billion and a half mark. The 1917 cut on the British Columbia coast alone is estimated at close to a billion feet.

The mills last year cut a lot of heavy timber for shipbuilding. Conditions on the prairies were also fairly good and a good deal of lumber was shipped there. Although the export trade was fair, the shortage of ships curtailed the total volume of business.

The increase in the price of labor and supplies, and all classes of mill machinery and accessories having gone up in price, have been responsible during the year for increased lumber prices. Millmen hold out no hope that conditions will be any better during this year, and higher lumber prices may be looked for in 1918.

Some spruce is being cut locally for aeroplane construction, but there is not so much spruce in this section of the province as is supposed. The bulk of the spruce supply of British Columbia lies in the north, and it will be the northern mills which will cut most of the spruce for aerial service. The Munitions Board is now working out a plan for securing large quantities of this spruce for shipment east.

**Submarine Boat Corporation Building Steel Ships.**—The keel of the first of the steel ships in the Submarine Boat Corporation's yard at Newark, N.J., was laid last Thursday by Edward M. Hurley, chairman of the Shipping Board. The programme calls for completion of 150 steel ships in Newark yards. The Newark Bay plant is one of the largest in the United States and was over 90 per cent. completed in 67 days. It will be possible, officials stated, to have 28 ships under construction at one time in the yards.

# ANNOUNCEMENT

Our Service Department, realizing the necessity for securing equipment for the manufacture of shells owing to the difficulties attendant on the importation of Machine Tools from the United States, have purchased the Drawings, Patterns and jigs of the famous

## "Montreal Shell Lathe"

**FOR BORING AND TURNING 6" AND SMALLER SHELLS**

This Lathe was designed and developed by the Montreal Foundry & Machine Co., and has attained an unexcelled reputation among Munition Manufacturers on 6" Shell Operations.

We have completed arrangements for the manufacture of this Tool with a well known Canadian Machine Tool Manufacturer and expect to be making deliveries in the near future.

Our SERVICE DEPARTMENT will be pleased to send you specifications, prices and deliveries.

## A. R. Williams Machinery Co., Ltd.

**64-66 FRONT STREET W., TORONTO**

# PRACTICALITY

AFTER fifteen years' study of the Miner's and Lumberman's wants, we know just what is and what is not required in tools for them.

Practicality has been the keynote of our organization. Experience has aided us in eliminating all unnecessary parts and in perfecting the design of our tools.

The use of best material and finest workmanship enable us to manufacture tools that are unexcelled.

We make a complete line.

Write us for prices.

**J. W. CUMMING & SON, LTD.**
NEW GLASGOW, - - CANADA
*Wood or Steel, let Cummings make it.*

# Cost Reducers for Shell Makers

SPECIAL PURPOSE SHELL TOOLS

Designed for use in our own Factory and found so satisfactory that other Shell Factories have asked for and been supplied with them:

Boring Lathes
Base Boring Lathes
Waving Lathes
Band Turning Lathes
Hydraulic Band Presses
Shell Grinding Machines
Shell Cleaning Machines
Undercutting Machines
Finish Tapping Machines
Inside Profiling Machines
Nicking Machines
Centering Machines

We can supply any of the above complete, ready for use, **at about half the cost of ordinary tools for the same purpose**, or we can furnish you with **a complete set of castings** ready for you to machine and set up.

We have sold these to many Shell Factories in Canada, and have had many testimonials regarding their good qualities and economy in use.

## Marsh & Henthorn, Limited

# INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## ENGINEERING

**Toronto, Ont.**—Plans have been drawn for the erection of a one storey addition for the Canadian Fairbanks Morse, Ltd., Bloor Street, to cost $4,000.

**Toronto, Ont.**—A $6,500 building permit has been issued for a one-storey brick foundry to W. H. Banfield & Sons, to be erected at 372 Pape Avenue.

**Toronto, Ont.**—The Spruce Falls Pulp & Paper Co. have acquired pulp limits in the Kapuskasing District, Northern Ontario, and will erect a pulp and paper mill.

**Toronto, Ont.**—The Holden Morgan Co., 579 Richmond Street, West, is having plans prepared for the erection of a building to cost $4,000 to manufacture munitions.

**St. John, N.B.**—Contracts for the electrical equipment for the Municipal General Hospital have been let, but tenders are being received on boilers, pumps, valves and fittings, etc.

**Winnipeg, Man.**—The Vulcan Iron Works, Ltd., will build an addition to its plant to cost $65,000. Tenders are being received by Woodman & Cubbidge, architects, 302 Lindsay Building.

**Toronto, Ont.**—Permission has been granted to the Cluff Ammunition Co. to construct a one-storey steel frame and corrugated iron cooling and shipping plant at 28 Atlantic Avenue to cost $10,000.

**Toronto, Ont.**—The Bond Engineering Works, formerly the Queen City Foundry, will build an addition to their plant on Cherry Street at a cost of $8,500. Contracts for the building have been let.

**Toronto, Ont.**—The Canada Type Foundry has been granted a permit by the City Architect's Department for the erection of an addition to their factory at 70-72 York Street. The cost of the addition is placed at $18,000.

**Regina, Sask.**—Damage to the amount of $30,000 was done at the Imperial Oil Co. plant last Thursday afternoon when the condenser box between stills seven and eight exploded. Fire resulted, burning a considerable quantity of oil. One workman was slightly injured. The company's fire department was able to cope with the flames.

**Toronto, Ont.**—The following permits have been issued to the British Forgings, Ltd., for additions and alterations to their plant at the corner of Liberty Avenue and Atlantic Avenue:—Storage buildings and addition to forge shop, one-storey frame and galvanized iron, to cost $15,000; one-storey frame and galvanized iron addition to forge shop at a cost of $[illegible]; one-storey frame and galvanized iron garage, $1,000; one-storey steel and galvanized iron addition to storehouse, also addition to office, to cost $1,000; pump house and office for munitions plant, $1,200; one-storey frame and galvanized iron building, to cost $2,500.

**Windsor, Ont.**—Representing the Canadian Steel Corporation, Mr. O. E. Fleming, K.C., at a meeting of the Border Utilities Commission, held last Thursday, made an announcement that official Governmental sanction had been received for a new water works system to serve the Town of Ojibway, where the Canadian Steel Corporation is engaged in the construction of a large steel plant. The plans for the water works system were submitted some time ago, Mr. Fleming stated. An intake pipe to be laid 250 feet out into the Detroit River will bring the water to the pumping and chlorination station for distribution.

**Toronto, Ont.**—The Ontario Government will develop big pulp and paper industry in the Kapuskasing district. Hon. G. Howard Ferguson has awarded to Messrs. Munday and Stewart, of 84 King Street east, who are understood to be representing American interests, the right to cut pulpwood and timber upon the Kapuskasing pulp and paper limit. The company to be formed will be required to erect at Kapuskasing a pulp mill costing with machinery and equipment not less than a million dollars; to operate it so that the daily output shall be not less than 100 tons of pulp, and to employ an average of 200 hands for ten months of the year. The company will also be required to erect a paper mill with a daily capacity of 75 tons a day whenever directed by the Government. The winning tender offered the government a flat rate of 75 cents per cord for all pulpwood and $15 a thousand for pine.

**Montreal, Que.**—F. G. Daniels, general manager of the Dominion Textile Co., announced recently that work on the new St. Lambert factory would be started during the coming summer. The destruction of the Halifax mill has made it necessary to hasten the South Shore plans, and while the operations during the coming summer will not be on an extensive scale it is proposed to erect a weave shed and the preparatory buildings during the summer. The agreement entered into with the town of St. Lambert provides for a commencement of construction work two years after peace has been declared. The new plant is to be built of reinforced steel and concrete, and will cost something like $3,000,000. Mr. Daniels explained that it would not be feasible to go ahead with any extensive building at the present time in view of the prevailing cost of material and machinery. He explained that restrictions placed on the manufacture and export of machinery from England made it practically impossible to carry on extensive construction just now.

## GENERAL

**Calgary, Alta.**—The Alberta Flour Mills will build a flour mill to cost $1,500,000.

**Montreal, Que.**—The Dominion Cement Co. contemplate building a plant to cost $100,000.

**Toronto, Ont.**—The W. G. Hunt Co. will build a factory on Dundas street to cost $10,000.

**Watford, Ont.**—The Andrews Wire Co. contemplate the erection of an extension to their factory.

**Deseronto, Ont.**—The Dominion Match Co. have started work on the construction of an addition to their factory here.

**Paris, Ont.**—The Alabastine Co., whose factory was gutted in a recent fire, contemplate rebuilding. Approximate cost, $35,000.

**Brockville, Ont.**—On Dec. 18 the Anvern cheese factory, located on the old Hough farm, at Fairfield, was burned to the ground. The cause of the fire is unknown. The place was owned by Samuel Walker. The loss will be covered by insurance.

**Winnipeg, Man.**—Entailing a loss estimated at $250,000, the large terminal elevator of the Northern Elevator Co., in St. Boniface, containing 80,000 bushels of grain, was completely destroyed by fire on Dec. 22. The fire originated under the dryer. Several workshops and storehouses in connection with the elevator were destroyed.

**Oshawa, Ont.**—Oshawa Town Council last Tuesday decided to submit a by-law to the citizens to give the Thornton Rubber Co., composed of Toronto business men, a fixed assessment of $5,000 per annum on the premises of the defunct Ontario Malleable Steel Range Co. for a period of ten years, with a cash bonus of the end of that time of $10,000, should the company carry out all its undertakings. The new industry will engage in the manufacture of waterproof textile goods.

## MUNICIPAL

**Belleville, Ont.**—The Town Council contemplate the installation of an electric pump.

**Renfrew, Ont.**—The Town Council contemplate the purchase of pumps for the waterworks.

**Brussels, Ont.**—The town is anticipating the installation of a new electric light plant shortly.

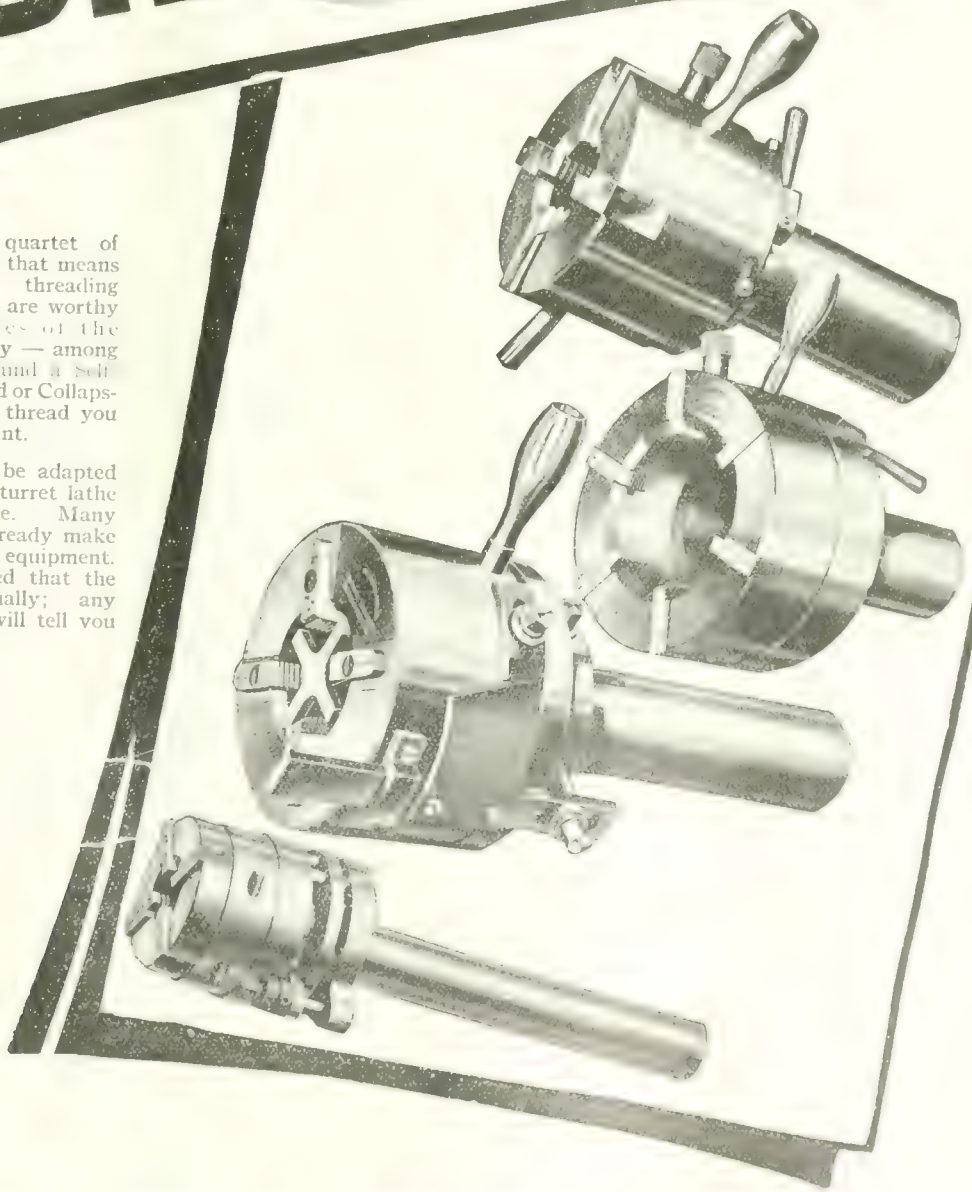
**Lumsden, Sask.**—The local electric light and power company will be purchased by the Town Council at a cost of $7,000.

**New Liskeard, Ont.**—The ratepayers will vote on a by-law on January 7 to

# GEOMETRIC DIE-HEADS

HERE'S a quartet of die heads that means death to threading trouble. They are worthy representatives of the Geometric family — among which can be found a Self-Opening Die Head or Collapsing Tap for any thread you could possibly want.

These tools can be adapted to any make of turret lathe or screw machine. Many manufacturers already make them standard equipment. We are convinced that the rest will, eventually; any Geometric user will tell you why.



## THE GEOMETRIC TOOL COMPANY
NEW HAVEN CONNECTICUT

**Canadian Agents: Williams & Wilson, Limited, Montreal; The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg and St. John, N.B.**

raise $1,475 for the purchase of road machinery.

**Galt, Ont.**—By-law will be submitted to the ratepayers on Jan. 1, for an extension to waterworks system, costing $18,558.

**Bassano, Alta.**—The Town Council contemplate the purchase of an electric pumping unit, costing approximately $2,000.

**Brantford, Ont.**—The Town Council has passed the following by-laws: $100,000 for waterworks improvements, and $6,500 for purchase of new school site.

**Ottawa, Ont.**—It is proposed to spend $128,000 for construction of a new bridge over the Rideau River at St. Patrick Street. A by-law will be voted on at the elections on January 7.

**Alliston, Ont.**—The ratepayers will vote on a by-law on January 7 to authorize an expenditure of $6,000 for elecrifying the pumping plant of the town of Alliston. J. E. Addis, town clerk.

**Hamilton, Ont.**—The ratepayers of Barton Township will vote on a by-law on January 7 to raise $55,000 to purchase necessary material and equipment for installation of electric light and power system.

**Perth, Ont.**—The municipality propose to raise $120,000 by municipal debentures and to purchase the local electric and waterworks plant from the present owners, the Canadian Electric and Water Power Co.

**Owen Sound, Ont.**—The King Shoe Co. propose to establish a factory here if the town will guarantee bonds for $30,000. A by-law will be submitted to the ratepayers on January 7 in connection with this proposition.

**Whitby, Ont.**—The following by-laws have been passed by the Town Council: $1,150 for construction of sewer laterals; $3,200 for low level pumping station; $5,700 for extension waterworks and electric light.

**Forest, Ont.**—A by-law will be submitted to the ratepayers on January 7 in connection with the purchase of an electric fire engine, apparatus, appliances and appurtenances for fire protection, to cost $8,500.

**Toronto, Ont.**—The Ontario Railway and Municipal Board has aproved of the by-law of the Township of York with regard to an application to lay water mains on four streets. These mains will be laid on Rogers road, Lambton avenue, Dufferin street and St. John's road, and will be 12-inch size. They will connect with the city waterworks system, and the city is suppling the water, as agreed by contract.

**Simcoe County, Ont.**—The following [illegible] York pending the return [illegible] America of Lord Northcliffe, is on the Imperial Munitions Board and also president of the Dominion Textile Co., Montreal.

**H. C. Opie,** sales agent for the Arthur by-laws of municipalities have been guaranteed by the Simcoe County Council: Midland, $25,000 aid to the Midland [illegible] for patriotic grants; Collingwood, $13,000 for patriotic purposes; $9,000 under Debenture Act of 1899; $3,500 for cement sidewalks, curbs and gutters; Creemore, $1,600 for school building and hydro construction.

**Toronto, Ont.**—Works Commissioner Harris has reported to Mayor Church that the contractors for the Don section of the Bloor Street Viaduct had completed their work, which had been accepted. As soon as weather conditions permit the Works Department will proceed to lay foundations for the car tracks and the permanent pavement. Although many residents in Wards One and Two would like to have the new thoroughfare opened for pedestrian traffic immediately, it cannot be done this winter.

**Ottawa, Ont.**—Commissioner Macallum has written the Board of Control that the estimate of $128,000 placed in the by-law which is to be submitted to the ratepayers as the cost of a new bridge over the Rideau River at St. Patrick Street was not supplied by his department. A three span steel arch bridge would cost $190,000, he said, and a four span bridge $180,000. It is now too late to have the amount named in the by-law changed. It is suggested, however, that the Ottawa Electric Railway Co. may be expected to pay part of the cost of the bridge.

## PERSONAL

**Frederick G. Clarke,** president of Clarke & Clarke Ltd., leather manufacturers of Toronto, died suddenly in Baltimore, Md., recently while on his way to Florida for the benefit of his health.

**John M. Park,** member of the boilermaking firm of Park Brothers, and one of Chatham's most prominent business men, died at his home on Queen Street, Chatham, Ont., on Dec. 24. He was 57 years of age.

**Sir Charles Gordon,** who has been appointed to represent the British Govern- Balfour Co., Ltd., of Montreal, has been on a six weeks' trip through the Eastern Provinces, and while on this trip had the memorable experience of being one of those who survived the terrible disaster at Halifax. While sitting quietly in a room at the hotel, Mr. Opie suddenly found himself blown through an opening from which the door had just been torn. Before leaving the stricken city Mr. Opie aided in the relief work for some time after the accident.

## TRADE GOSSIP

**The Sherbrooke Machinery Co.** of Sherbrooke, Que., has increased its capital stock from $20,000 to $100,000.

**The Consumers' Metal Co.** has increased its capital stock from $40,000 to $150,000.

**The Roelofson Elevator Works,** Galt, Ont., have the contract for elevator equipment for manufacturing plant for the Alabastine Co., Paris, Ont.

**Building Situation at Windsor, Ont.**—During the year 1917, the city engineer of Windsor, Ont., issued 616 building permits having a total value of $1,155,000.

**Building Statistics for Regina.**—The building statistics for the City of Regina, Sask., show that for the year 1917, up to Nov. 30, there were 174 permits issued having a total value of $415,410.

**Substitute for Platinum Found.**—Rhotanium, the name of a new substitute for platinum, is an alloy of metals of the platinum group, and is being used for crucibles, ignition tubes and thermo couples.

**Chief Mining Provinces in Canada.**—Ontario and British Columbia are the chief mining provinces of Canada, the former producing 45.32 per cent. and the latter 22.66 per cent. of the mineral output of the Dominion in 1916.

**No Change in Coke Prices.**—A report from Washington states that there will be no general revision of coke prices for the year 1918. Fuel Administrator Garfield last Saturday issued an order continuing in force the prices fixed last September.

**The Jonathan Bartley Crucible Co.,** Trenton, N.J. announce that they have engaged the services of E. P. Welton of Stamford, Conn., to represent them in the sale of their line of crucibles and reorts through New England and Canadian trritory.

**Iron Ore Shipping.**—Authorities say that mines in the Lake Superior district will be in a position to produce and ship 70,000,000 tons of iron ore during the 1918 season. This would compare with a high record of 64,734,198 tons of ore shipped in the 1916 season.

**U. S. Government Fixes Price of Silver.**—A price to be paid by the United States Government for silver in agreement with western producers has been agreed upon and will be announced soon. It is said to be satisfactory to the producers and will be about one dollar an ounce.

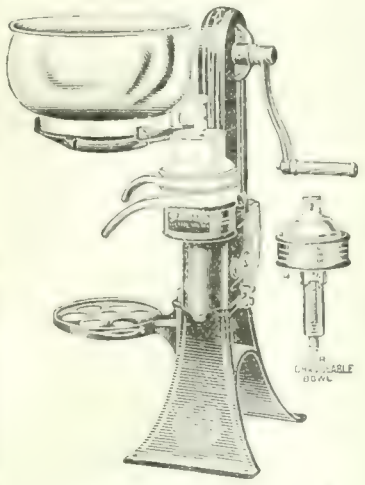
**Building Situation At Three Rivers.**—The value of building permits at Three Rivers, Que., for 1917 shows a decline when compared with the two preceeding years, the figures being as follows; 1915, $484,205; 1916, $537,345 and 1917, $422,950. The prospects for 1918, however, are improving and a better year is looked for than in 1917.

**Building Situation in Winnipeg.**—The building operations in Winnipeg for the year 1917 include 1,231 permits and 1,263 buildings erected at a cost of $2,206,500. City Architect Robert E. Davies predicts that the building operations during the coming year will be about the same as in 1917.

**License Not Needed for Goods in Transit.**—The war trade board at Washington has advised the Department of Trade and Commerce, Ottawa, that commodities passing through the United States in transit and not for consumption in that country do not require an import license. United States collectors of customs have been instructed to this effect.

**Iron Ore Shipments On Great Lakes.**—The closing of the season's navigation on the Great Lakes shows that the water

# This Machine Abounds With Live Selling Features



It is reasonable to expect heavy sales with a machine that outskims all others.

The Standard proves its claims by Canadian Government Dairy Schools Tests.

The Standard gets all but the last pound of butter-fat in five tons of milk skimmed. That record is convincing to both dealers and to the ultimate user. The result, as we have proven by experience, means splendid business. It will pay you to handle the

**Made in the British Empire** *Standard* CREAM SEPARATOR

Besides, the Standard has many other exclusive features that clinch sales. Its capacity may be changed from the [illegible] hour sizes up to 100 gallon capacity by simply changing the bowl and accessory parts. A new machine is not necessary.

Repair Parts carried in stock at chief distributing centres.

Our illustrated literature describes every selling feature in detail, including the self-oiling system [illegible] how the butter made from the cream the Standard separates is superior in firmness, due to our exclusive curved wing centre piece, etc., etc. Tests are fully described.

Catalogue and prices will be sent to responsible [illegible] are F.O.B. Montreal, St. John or New York. Immediate shipments can be made of all sizes.

Renfrew Household Scale [illegible] handy; guaranteed accurate; furnished with or without Canadian Government inspector's certificate [illegible] lbs. Scales are shipped with parts knocked down and all parts are numbered for easy assembling.

AGENTS: We invite correspondence from responsible agents to handle the Standard Cream Separator and Renfrew Household Scale. Write for descriptive catalogues and price lists. Careful packing and prompt shipments are guaranteed.

**The Renfrew Machinery Co., Limited, Renfrew, Ontario, Canada**

# Are you the man we need?

SOMEWHERE in Canada there's a man we would like to meet.

He may be a machinist, an office man, timekeeper or salesman. He may not be able to boast a college education, but so long as he has ambition and good judgment a lack of the higher education will not prove a handicap.

The man we want is a man whose fighting spirit would have carried him to France had he not been prevented. A man with energy and push and ambition and resourcefulness.

The work we have in mind for such a man would not be congenial at first (to a man lacking the qualities named) but it would prove the open door to splendid opportunities later (and not so very much later either, perhaps).

If you are not satisfied with your present outlook and feel, right down in your heart, that you could SELL (with proper direction), then write us.

If you are a hustler, prove it by replying promptly to this advertisement, and to prove you are thorough-going, give full particulars as to age, experience, present salary, etc. Replies will be considered strictly confidential.

Box 364,
CANADIAN MACHINERY.

**MANUFACTURERS EQUIPMENT COMPANY**

75-179 N. JEFFERSON STREET, CHICAGO, ILL.

Canadian Agents: J. R. Stone Tool and Supply Co., Detroit, Mich.
New York: J. R. Stone Tool and Supply Co., 30 Church Street

movement of iron ore in 1917 reached 62,498,901 tons, against 64,734,198 tons in 1916, the record year, and 46,318,804 tons in 1915. Probably 2,000,000 tons have been moved by rail this year, making total Superior shipments approximately 64,500,000 tons, or about 3.50 per cent. under the 1916 grand total.

**C. P. R. Has Built Many Cars.**—During this year the Canadian Pacific Railway has built over sixty thousand box cars in addition to many ordered from outside. The business of the railroads has increased so enormously since the Government undertook to supply Great Britain with foodstuffs and munitions, there is a considerable scarcity of cars, though the situation is being ameliorated through the efforts of the Canadian Railway War Board.

**Hamilton, Ont.**—The Canadian Cartridge Co. of this city has received from the United States Government an order for the manufacture of brass cartridge cases. Owing to the recent curtailment of munitions manufacturing in Canada the Canadian Cartridge Company has contemplated a partial shutting down, but it was intimated that the new order from Washington is large enough to assure the extensive staff of this concern plenty of work for many months to come.

**B. C. Spruce for Airplanes.**—Hon. T. D. Pattullo, Minister of Lands for British Columbia, stated recently that private enterprises have made definite arrangements to complete plans whereby about ten million feet of airplane spruce a month will be procured and placed on the market for disposal along the essential channels. Other concerns are making tentative plans which will be certain to materialize just as soon as the engineers now making practical investigations succeed in making their findings.

**Canadian Firm Extends Operations to U. S.**—The A. R. Williams Machinery Co., Toronto, in order to handle the increased demands on their munitions service department by American manufacturers, have incorporated the A. R. Williams Machinery and Supply Corporation of Buffalo, N.Y. T. B. Reid, formerly manager of the machine tool department of the Toronto house, will be in charge, supported by a number of Canadian experts. The offices of the Corporation are in Fidelity Building, Main Street, Buffalo.

**Railway War Board Aids Coal Saving.**—The Canadian Railway War Board calculates that in the measures it is taking for the elimination of passenger trains it will be able to save 100,000 tons of coal. Without incommoding the public there will be elimination wherever possible. The Railway War Board has gone carefully into the matter of passenger service, with the thought of conservation in [illegible] power. The crews liberated from passenger trains that are cut off may be [illegible]

**To Expand British Trade.**—The British Board of Trade have had under consideration the [illegible] to establish Trade Commissioner service in the British Empire. According to recent press despatches from London, it is now proposed to increase the number of Trade Commissioners in several of the Dominions, and to appoint commissioners in India, and in some of the Crown colonies and protectorates. It is understood that several commissioners are being appointed in Canada, which has hitherto been served by only one British Trade Commissioner.

**Flotation System of Canadian Invention.**—A contract has been let for the installation of a flotation plant on a molybdenite property near Amos, on the Transcontinental Railway and about twenty miles from the St. Maurice lines. The Groch centrifugal system of flotation is attracting more than ordinary attention. Arrangements have been made for the installation of a machine at the McIntyre Porcupine, the second largest gold producer in the Dominion. The machine will be for experimental work. The Groch machine is the product of Canadian inventive genius and is manufactured by Canadian labor.

**Winnipeg Hydro Has Good Surplus.**—The report of the Winnipeg Hydro-Electric department for the month of October shows a surplus to date of $144,537.69 over operating expenditure. The revenue for the month of October amounted to $91,907.75, with operating expenses figuring at $84,650.97, leaving a surplus for the month of October of $7,256.78. The six months ending October 31, however, showed a deficit of $23,640.28, but as there was a surplus of $168,177.97 on hand at the beginning of the year, there still remains to the credit of the Hydro-Electric system a net surplus of $144,537.69.

**Steel Price Schedule Extended.**—The fear that the present price schedules now prevailing in the iron and steel trade in the United States will be altered is gone and the trade has the satisfaction of knowing that it will enter 1918 upon established bases. The War Industries Board has recommended to the President the indefinite extension after January 1 of the prices fixed last September. It is expected that the President will issue a proclamation extending the present schedule. Whether a definite period will be named remains to be seen, but it is believed that some readjustments will come within the next ninety days.

**Two Patrol Boats Launched at Polson's.**—At 1.30 o'clock on Christmas afternoon two Government fishery patrol boats were launched at the Polson Iron Works. One was christened by Miss Church and the other by Miss Russell, daughter of John S. Russell. Those attending the ceremony included Mayor Church, Douglas Eby, Lieut.-Col. J. B. Miller, Sanford Evans, Ottawa; Holt Gurney, Mr. and Mrs. Osler Wade, Mr. and Mrs. T. G. McConkey, and Jos. McGregor. In order to launch the boats, each 130 feet in length, the ice in the bay had to be cut through to make a clearing. Both boats will be completed [illegible] time navigation opens.

**Sherbrooke, Que., Building Statistics.**—The building permits for 1917 amount to $254,000. This amount shows a decrease, compared with last year's operations, which is due to high cost of materials and scarcity of labor in this line; owing to these facts, many large contracts had to be postponed, and the number of permits issued were only for urgent works, which kept the building trades very busy during the season. For 1918 the outlook is as follows: As long as the war lasts it is not expected that any very large contracts will be proceeded with, but tre usual repairs and alterations, and erection of small buildings will no doubt be undertaken, there being a great demand for tenement houses and small dwellings.

**Cheaper Power at Orillia.**—The Water, Light and Power Commission has made a reduction of 20 per cent. in the rates, which will mean a total saving of over $12,000 per annum. This was rendered possible by the completion of the new plant at the Swift Rapids, which provides all the power the town requires for its industries, whereas formerly a large quantity had to be purchased from other sources in addition to what was obtained from the old plant at the Ragged Rapids. The power rate is now $13.50 per horse-power per annum for ten-hour power and $18 per horse-power for a 24-hour service. The light rates are correspondingly low, the consumers having their choice of flat or meter rates.

**C.A.S.E. Exhibitors' Association.**—The 29th Annual Convention of the Canadian Association of Stationary Engineers will be held at London, Ont., June 25, 26 and 27. As unanimously decided at the last anual meeting, the usual exhibition of power plant supplies will be held. The feeling of the meeting was that the convention and exhibition teach economical and efficient methods in the power plant and thus assist in the national effort to induce industrial production. London is a good centre for the convention, being a large growing city in the centre of Western Ontario, with distributing lines leading to all the important towns and cities in the Western part of the province. Full particulars regarding hall and other arrangements will be available at a later date. The secretary is Gordon C. Keith, 32 Colborne Street, Toronto.

**Situation in the Leather Trade.**—The chairman of the Tanners' Section of the Board of Trade, in his address at the annual meeting held in Toronto last week, said: "I believe that during the last eight months conditions generally throughout the leather market have not been satisfactory, and this may be accounted for to a considerable extent by the great increase in the cost of labor, tanning materials and fuel for power purposes, also the placing of an embargo in February by the British Government against shipments of leather to the British market, which embargo still continues, but figures show also that there is a considerable increase in the amount of leather shipped from Canada to Australia and New Zealand. There can be no question but that

the tanning industry in Canada is firmly established, as there has not been a single assignment or failure during the year."

**Move to Relieve Freight Congestion.**—The United States railways, like the Canadian, are cutting down their passenger traffic radically. Even on the main arteries of passenger travel, such as those between New York and Washington, two or three trains a day have been taken off single roads, because the passenger trains were blocking the freight service. One measure to avoid congestion of freight at ports, effective for the last three years in Canada, has just been adopted by the American lines. New York and the other Atlantic ports in the United States have been and still are badly jammed with freight awaiting shipment. Now, however, the situation is being relieved by the adoption of the Canadian system of refusing to accept freight for export, unless the shipper can show that space on ship has been reserved for it ahead of time. This system is now in full operation, under the direction of the export division of the general operating committee of the American Railway Board, which has offices in New York.

## ELECTRICAL

**Parkhill, Ont.**—The Town Council propose installing a hydro-electric system here.

**Hamilton, Ont.**—The ratepayers of Barton Township will vote on Jan. 7 to sanction an expenditure of $55,000 to purchase necessary material and equipment for installation of electric system.

**Perth, Ont.**—The Hydro-Electric Commission proposes building a transmission line between Perth and Smith's Falls in order to supply the town with power. It is proposed to change over the present generating stations and distributing system from 133 cycles to standard 60-cycle equipment.

## MARINE

**Toronto, Ont.**—The Dominion Shipbuilding Co. has taken out a permit for the foundation of their new building at the foot of Bathurst Street; foundations to be of timber and piles to cost $15,000.

**Victoria, B.C.**—It is reported that the Foundation Co., will establish another large wooden shipbuilding plant on the North Pacific Coast. The location of the proposed new plant had not definitely been decided upon but it was intimated that it rested between Puget Sound and the Columbia River districts.

**Esquimalt, B.C.**—Yarrows, Limited, have been awarded the contract for repairing the Grand Trunk Pacific liner Prince John, which ran aground near Skidegate in the Queen Charlotte Islands two weeks ago. The damage is only of a minor nature; three or four shell plates forward will have to be renewed. The job of placing the Prince John in seaworthy condition again will occupy about a week. It will then go north to resume the service between Prince Rupert and the Queen Charlotte Islands.

# CONTRACTS

**Toronto, Ont.**—The Jackson Lewis Co., Toronto, has been awarded contract for the erection of an addition to cost $30,000 to the factory of Canadian Aeroplanes, Ltd., Dufferin Street.

# INCORPORATIONS

**The Okotoks Electric Co.** of Calgary, Alta., has been incorporated with a capital of $20,000.

**The King Shoe Co.** has been incorporated at Ottawa by John S. King, W. F. Marquardt, and F. W. Wenegast, of Toronto, to manufacture boots and shoes at Owen Sound, Ont., with a capital of $100,000.

**Rae Machine Tool Works Ltd.** have been incorporated at Toronto with a capital of $45,000 to manufacture machinery and appliances of all kinds at Hamilton. The provisional directors are Willis B. Sturrup, John J. Duggan and Craig McKay.

**Douglas Bremner & Co.** has been incorporated at Ottawa by W. S. Johnson, W. S. Wilson and A. R. Hall, all of Montreal to carry on business as civil and hydraulic engineers, foundrymen and machinists, etc., at Montreal with a capital of $50,000.

**The Wedgerite Piston Ring Co.** has been incorporated at Ottawa with a capital of $49,000 to manufacture a patent piston packing, also engines and motors of all kinds at Montreal. The incorporators are Ulric and Ernest Duchesne and Charles A. Gareau, all of Montreal.

**The Great Lakes Steel Corporation** has been incorporated at Ottawa by Frank Regan, William N. Irwin, and E. J. Murphy, all of Toronto, to manufacture iron and steel products of all kinds at Owen Sound, Ont., with a capital of $1,000,000.

**The Eugene F. Phillips Electrical Works,** Montreal, has changed its name to that of Phillips, Ltd. The company has also been incorporated with a capital of $4,000,000 to engage in the manufacture of wire cables and electrical apparatus of all kinds.

**British Explosives Ltd.** has been incorporated at Ottawa by D. M. McLean, F. E. Westergard and A. C. E. Owen all of Ottawa, to manufacture explosives, chemicals, acids and fertilizers of all kinds. The chief place of business is at Ottawa and the capital is $50,000.

**The Newell Manufacturing Co.** has been incorporated at Ottawa with a capital of $45,000 to manufacture sheet copper, brass, steel, tinplate, etc., at Prescott, Ont. The incorporators are: Edgar A. Newell, William A. Newell, and Albert P. Newell, all of Ogdensburg, N.Y.

**Electric Smelting Co., of Brantford, Ltd.,** has been incorporated at Ottawa with a capital of $45,000 to manufacture steel castings by the electric furnace process at Brantford, Ont. The incorporators are H. M. McIntyre, John Ker and Philip H. Secord, all of Brantford, Ont.

**O'Connors Ltd.** have been incorporated at Ottawa with a capital of $100,000 to carry on business as steel and iron founders, tool makers and engineers. The chief place of business is at Montreal and the incorporators are Andrew P. O'Connor, Walter P. O'Connor, both of Sorel, Que., and Edward A. D. Morgan of Montreal.

**Imperial Oil Ltd.** has been incorporated at Ottawa with a capital of $50,000,000 to acquire, and take over as a going concern the refining and the business of marketing petroleum and its products now carried on by the Imperial Oil Co., with head office at Toronto. The incorporators are W. C. Teagle, C. O. Stillman and G. W. Mayor, all of Toronto.

# RAILWAYS

**Ottawa, Ont.**—Hon. J. D. Reid, Minister of Railways, has received information from the executives of the Canadian Government Railways at Halifax that the work of reconstruction is proceeding rapidly. At Pier "A" the grading for tracks is fifty per cent. complete and grillage is being made for sheds. At the dockyard some material is delivered and construction of buildings under way, and repairs being made to the naval hospital. At new Pier 2 repairs are far enough advanced so that hospital ships may be docked after the 26th. The elevator is expected to be in service by the 23rd or 24th. North Street station tower has been removed and the roof is being sealed.

# CATALOGUES

**Gravity Conveyors.**—Bulletin describing gravity conveying systems made by the Lawson Company, Boston, Mass. A number of colored illustrations show various applications of the Lawson system to suit different classes of service.

**A Sure Hit** is the title of an illustrated folder featuring the line of quarter-turn cocks made by the Homestead Valve Co., Homestead, Pa. Patriotism, Homestead, Economy are referred to as a three-cornered combination that always hits the mark.

**Three Jaw Air Chuck.**—The Manufacturers' Equipment Co., Chicago, have issued an attractive catalogue dealing with a labor saving device in the form of a three jaw air chuck. The principal features of this chuck are fully described while detail illustrations are given showing the mechanism.

**Machine Tools.**—The Bilton Machine Tool Co., Bridgeport, Conn., have issued a new series of bulletins describing an interesting line of machine tools including automatic gear milling machines, manufacturing milling machines, riveting machines and gear hobbing machines. Each size of the various types of machine is illustrated together with specification and full description. The bulletins are bound together in a loose leaf folder and gotten up in an attractive manner.

**Line Reaming Bearings.**—The Taft-Peirce Mfg. Co., Woonsocket, R. I. have issued a new bulletin No. 101, describing the Martell system of line reaming bear-

ings in preference to hand scraping of bearings to obtain true alignment. The bulletin deals with the necessity of true alignment, particularly in high speed machines such as gasoline motors, for which the reamer was specially developed, and proceeds to describe the construction and operation of the Martell reamer. All the parts of the reamer are illustrated and described in detail, special mention being made of its principal features. Special applications of the Martell reamer are also described and accompanied by illustrations showing its construction. Other illustrations show the reamer in operation on various classes of work for both large and small bearings.

## BOOK REVIEW

**Tests of Oxacetylene Welded Joints in Steel Plates.**—A series of tests of the strength of oxacetylene welded joints in mild steel plates has been completed by the engineering experiment station of the University of Illinois under the direction of H. F. Moore, Research Professor of Engineering Materials. Specimens were supplied by the Oxweld Acetylene Company of Chicago and tests were made in the laboratories of the Station at Urbana under three conditions of loading: (a) static load in tension (in a testing machine); (b) repeated load (bending), and (c) impact in tension (in a drop testing machine). For joints made with no subsequent treatment after welding, the joint efficiency for static tension was found to be about 100 per cent. for plates one-half inch in thickness or less, and to decrease for thicker plates. For static tension tests, the efficiency of the material in the joints welded with no subsequent treatment was found to be not greater than 75 per cent. The joints were strengthened by working the metal after welding and were weakened by annealing at 800 degrees C. For static tests and for repeated stress tests, the joint efficiency sometimes reaches 100 per cent.; the efficiency of the material in the joint is always less. This indicates the necessity of building up the weld to a thickness greater than that of the plate. The impact tests show that oxacetylene welded joints are decidedly weaker under shock than is the original material; for joints welded with no subsequent treatment, the strength under impact seems to be about half that of the material. In general, the tests results tend to increase confidence in the static strength and in the strength under repeated stress of carefully made oxacetylene welded joints in mild steel plates. The results of these tests have been published as Bulletin No. 98 of the Engineering Experiment Station, copies of which may be obtained without cost by addressing C. R. Richards, Director, Urbana, Illinois.

The physician was soliciting information from the patient's wife.

"Does he grind his teeth in his sleep?" he asked.

"Oh, no," said the wife. "He don't wear 'em to bed."

## SITUATIONS WANTED

GENERAL SUPERINTENDENT WITH PRACtical and commercial [illegible] experience, desires change. One having considerable munition experience, principally shells of [illegible]. Box [illegible] Canadian Machinery. (c23m)

EXPERIENCED METAL PATTERN MAKER desires change. Experienced on lathe and bench and motor plates; good on tool and machine work. Box 362, Canadian Machinery. (c1m)

## SITUATIONS VACANT

ASSISTANT WANTED WITH PRACTICAL technical and commercial machine tool experience, by large exporters of machine tools; give age, experience and salary. Box 361, Canadian Machinery. (25)

## FOR SALE

1 [illegible] x 26 BROWN & SHARPE SPUR GEAR cutter, splendid shape, with countershaft and arbors. Box 365, Canadian Machinery. (c2m)

THREE TONS COLD ROLLED STRIP STEEL, drawing quality 8" wide, .065 thick. Dillon Manufacturing Co., Oshawa. c1m

FOR SALE CHEAP 16" SHAPER; 24 x 24 x 6 planer; two heavy duty roughing lathes for 6" shells; 1 Hall No. 6 cut-off machine; 1 2-ton heavy Morris chain block—all guaranteed and in first class condition. Dominion Machinery Co., Toronto. c24m

## WANTED

WANTED — GOOD SECOND-HAND GAP [illegible] (approximately 18" x 36", with long [illegible] to 4" centre. Also good used 24" or [illegible] turret, about 12" x 60". Turret [illegible] Box 367, Canadian Machinery. (c1m)

WANTED ONE NEWTON OR ESPEN-LUCAS second-hand cold cutting saw, with capacity for sawing sections up to 20" in diameter. Address Ellis O. Friedman, Inc., 82 State Street, Albany, N.Y. (c3m)

WANTED ENGINE LATHE, 18 TO 24-INCH x 10 or 12-foot bed. Give full particulars and price. Northwestern Iron Works, Regina, Sask. (c9m)

WANTED A GOOD, POWERFUL TURRET lathe for 4.5 shell work. Second-hand and in first-class order. Price must be low. Box 366, Canadian Machinery. (c26m)

WANTED DESIGNS, SHOP DRAWINGS, tracings, estimates, specifications made to requirements by experienced practical engineer and designer. Any mechanical proposition carried through. Box 363, Canadian Machinery. (c6m)

WANTED — COMPLETE BOLT AND NUT machinery to manufacture sizes ¼-inch diameter and up. Advise offerings in either second-hand or new. Box 360, Canadian Machinery, Toronto. (c2m)

## AGENTS WANTED

WANTED — LIVE REPRESENTATIVE TO handle good specialty; one who hasn't too many irons in the fire. Apply Box 348, Canadian Machinery, stating lines you now represent and the ground you are prepared to cover. c23m

WANTED—PARTY TO TAKE OVER CANAdian and European patents of good paying machine. The machine, which costs less than thousand dollars to build, is in daily operation in Pittsburgh steel mill, with a saving of thirty dollars per day. Apply to Box 356, Canadian Machinery. (c25m)

# Shell Machining Pitfalls--4.5 in. H.E., Marks VII. and IX.

By H. A. Wilson *

*The extent and duration of shell production has enabled considerable progress to be made in the standardizing of methods and devices whereby machining losses are kept at a minimum. There still exists some diversity of opinion, due probably to local conditions, regarding the superiority of certain routine or apparatus. The writer's opinions presented in the following article represent specialized practice which has proven satisfactory.*

WITH the revival of the shell industry in Canada, perhaps a few suggestions in reference to simple operations which have the faculty of causing trouble would help some contractors who have recently gone into the shell business for the first time, or who have started to manufacture a new type of shell. Thus in the following paragraphs the writer will try to describe briefly a few trouble savers and money savers which three years of experience have shown were good investments.

**Special Attention to Centering Base Ends**

Most firms, in the rough turning operation, support the base end of the shell with a tail centre. It is very important that the centering be carefully watched, so that this centre is absolutely concentric with the hole in the forging. A badly worn die used in the piercing operation in forging will sometimes leave small longitudinal ribs in the interior walls of the forging. A common method for centering in a lathe or under in drill press is to use a locating arbor, either solid or expanding, which enters the shell forging. Such ribs, as referred to above, will cause the centre to be more or less eccentric. Sometimes a hard bit of scale will throw the locator out. The shell should be thoroughly examined and if these obstructions exist they should be removed. A mechanical method is to use a rough form tool with a double blade operated by a drill press spindle.

If a shell, which has been centred off centre, passes through the rough turning and goes on to the boring lathes in nine out of ten cases there will be a thin wall and a thick wall and the boring tools will have a tendency to follow the hole. Some people claim to have overcome this by using a single tool in the bar on the first boring operation. This does overcome the difficulty as far as the straight portion of the bore is concerned, provided that the fixtures are sufficiently rigid to resist the tendency to "work" and "spring," but when the roughing and finishing form tools go into the bottom they form a pocket. To overcome this a tool to form the bottom of the bore has been designed. It is simply a double form tool about fifty per cent. longer in the body than the average tool. This costs money for high speed steel and it would appear that proper centering is the easiest and most economical method to adopt to escape the difficulties of a thin wall. No one has yet discovered a method of salvaging a shell with a thin wall.

*Manager, J. C. Wilson & Co., Belleville, Ont.

**Deductions from Rough Turning Experiences**

The writer's experience has been entirely confined to the British 4.5 high explosive shell. Rough turning was tried both with one tool and two tools, also at various speeds and on various diameters. Taking all things into consideration, economy in high speed steel, and sustained output, it was proved that one tool holds up better and will remove more steel at about 40 revs. per min. than at any other speed. A broad cutting surface is used and a coarse feed. The shell is turned one diameter from base to nose. One tool is sufficient.

**Face Base Square Before Boring**

No one need impress the experienced shell manufacturer with the importance of the weight in high explosive shells. The thickness of metal in the base has resolved itself into the determining weight factor. Boring is a final operation on one portion of the base. If the base has not been faced square with the rough turned body there is a chance of making a thin base, if the bottom of the shell is being used against a stop. It has been demonstrated that it pays to set up a machine to finish the base square just previous to boring.

**Boring and Nosing**

A few points on boring have been mentioned in the foregoing paragraph. Rigidity is one of the main requirements. The type of lathe which has a large cast iron spindle which will bore out to allow the shell to be chucked in the main bearing gives best results. The large bearing also shows but little wear. Nine out of ten turret lathes made for this purpose fall down under pressure of constant use. If a designer can get a turret that will not work loose, this type of fixture is to be preferred, and roughing and finishing can be completed with one chucking. Designs of satisfactory turrets are available, some which have given satisfaction over a long period of constant

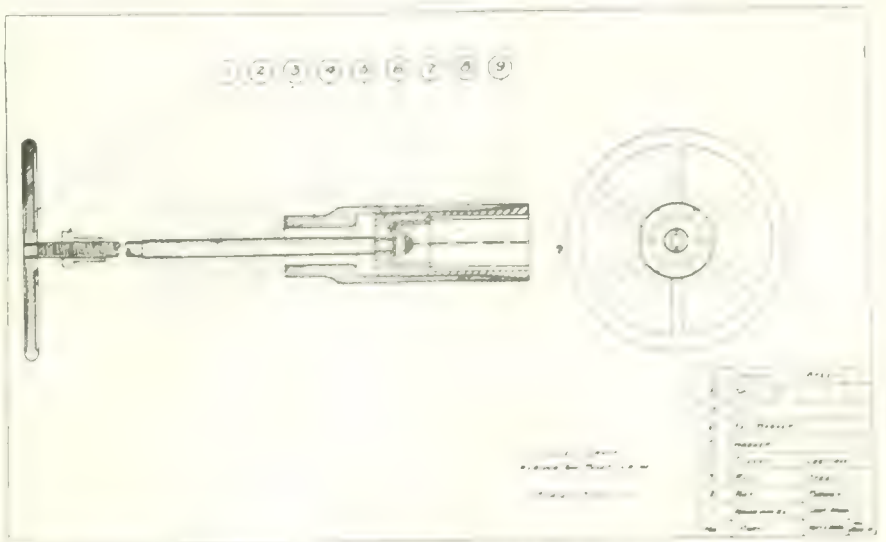

FIG. 2. TYPE OF [illegible] LARGE BOTTOM CAST IRON SPINDLE SHELL CHUCKED [illegible] AT REAR END.

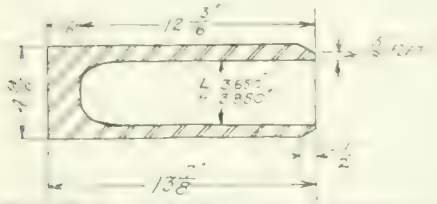
are. The main boring bar had in two diameter cast integral with a specially designed carriage having a long bearing on the ways of the lathe gives excellent results but only one operation can be completed on one lathe and roughing and finishing must be done on different machines which requires extra handling. This is not necessary on a shell of so small a calibre as the 4.5 in. howitzer.

Properly designed form cutters for finishing the bore are essential. Clearances, rakes, etc., are available at any one of a large number of shops.

In getting uniform results in nosing it has been found very useful to trim the nose end of the shell while it is in the boring lathe making all shells uniform in length within one thirty-second of an inch. It is also good practice to bore shells within a few thousandths of the low limit in diameter. This allows you to gain weight in case a short shell or thin base turns up. It also helps to guard against thin walls. Shells which are hard to bore smooth can be polished smooth in a grinder of simple design. Lathes boring 4.5 in. shells can operate at about 75 revs. per min. Feeds must



DIMENSIONS OF SHELL WITH CHAMFERED NOSE. READY FOR NOSING.

be adjusted to suit the hardness of the steel and whether finishing or roughing these feeds vary from one-sixteenth to three-sixteenths of an inch.

### Chamfer or Bell-mouth

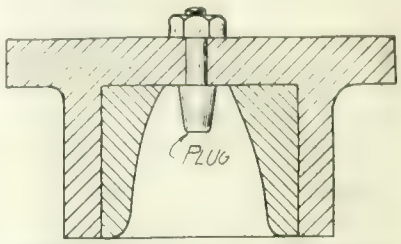
The nose is usually chamfered in the nosing operation. It is a question now as to the advisability of chamfering the outside of the shell or making it "bell-mouthed." Both methods give good results. The amount of metal removed has to be accurately determined by experiment so that approximately the correct amount is left to be properly formed in nosing. These general dimensions shown in the accompanying line cut are the ones which the writer feels safe in recommending, provided that a nosing die and plug of the dimensions shown are also used. To get these results the shell, after nosing, must have been "upset" so that its overall length is 13 1/16 in. Further the shell must be heated in a furnace uniformly. If hotter on one side than another when nosed, the cooler side will not act under the die as the hotter side and the probability is that the shell will have to be fitted with a socket. Similar defects in nosing will be encountered if the shell is heated lower down on one side than another. If the shell is turned from one quarter to one half turn every half minute to minute the heat will be found to be very uniformly distributed. The shell should be a white heat on the nose and all appearances of a glow should disappear at a distance of three and one half inches from the nose. As long as a shell is not burnt on the tip of the nose it is not too hot.

### Nosing Furnace

The furnace that has given the best all around satisfaction for heating 4.5 in. shells is an oil fired furnace of either the low pressure or high pressure type. Originally these furnaces were equipped with a cast iron front waterjacketed. To nose properly the later marks of 4.5 in. shells, there was great difficulty in getting the proper heat. Solid brick fronts were then tried. The shells were heated faster than the press could nose them and consequently shells were burned, and were thus spoiled. Several nosing sheds, and in some cases whole factories, were burned, from these overheated furnaces. A happy medium has been developed. This is in the shape of a cast iron front waterjacketed with one layer of brick placed behind it. Very satisfactory results have been obtained from this type of front and at a reduction in the consumption of oil.

The shell has a tendency to bulge if heated below a point three and one half inches from the nose. This bulge is later removed in the finish turn operation leaving a thin wall. If a shell is too cool on the nose and heated too far down this bulging becomes a serious factor. To get shells all nosed to a uniform length the shell is held in a heavy type hinged vie. This vise comes against the die and die holder and thus acts as a stop.

The question of whether it is advisable to chamfer the nose on the outside or make the shell bell-mouthed is a difficult one. The writer prefers to chamfer the outside as shown. This type of shell is nosed with less power and the chamfering offers less wear to the die. It, however, is harder on the plug. The metal seems to grip the plug and heat it to a red heat. When the shell is removed the downward pull on the hot plug seems to draw it out forming a thin neck into which the metal is forced and the shell thus grips the plug. A high speed steel plug properly tapered does not lose its temper at a red heat and thus resists and overcomes the difficulty. Plugs can be arranged to be easily removed and thus if a plug becomes distorted it can be replaced. Plugs can be



TYPE OF CHILLED DIE USED FOR NOSING SHELLS.

repaired and used many times. The bell-mouthed shell gives more die trouble and less plug trouble.

A water cooled die is not an unqualified success, and cast iron chilled dies have largely replaced hardened die block steel dies. Thus the least troublesome way to cool a die is to shoot water right up into it for a few seconds after each shell is nosed and previous to lubricating it. The high speed steel plug does not seem to be harmed by this treatment and the chilled cast iron die seems to be improved. To lubricate the plug and die a cheap form of foundry facing is used, mixed with any low-grade oil, which does not give off too much smoke. A small hole through the centre of the plug one quarter inch in diameter will carry away a lot of smoke. Three thousand pounds hydraulic pressure on a press with 12 in. diam. plunger is used.

### Gauging After Nosing

Immediately after nosing it is good practice to run a high speed drill 1 11/16

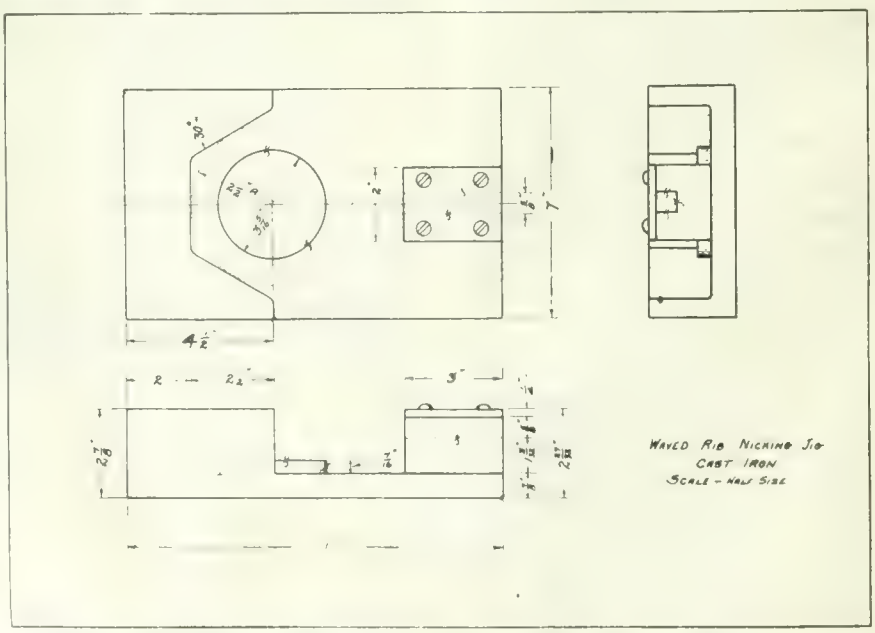


FIG. DEVICE OR JIG FOR NICKING THE WAVED LINES IN THE DRIVING BAND GROOVE. THIS JIG HOLDS THE NICKING CHISEL IN PLACE.

in. diam. into the nose. The amount of metal in the nose is then gauged, also it is noted if it has been located symmetrically with the axis of the shell. If any irregularities appear the shell is laid aside and later rectified by being nosed again with a special plug somewhat larger than the normal size which displaces the eccentric metal and allows the shell to be recovered with but little or no expense.

### Operations on Nose

The succeeding operation is to machine the nose. A boring bar with a single tool roughs out the surplus metal. Next bar carries a flat, double blade reamer which leaves the hole in the nose a few thousandths smaller than the finished diameter of the container seat. A similar type of reamer, floating in its bar, next reams the nose to the diameter of the tips of the threads and this bar works to a stop which allows it to go only to that point which is later to be recessed. The rough boring tool carries a small tool which levels the nose. Thus three bars complete this operation.

### Finish Turning

Finish turning comes next. A very accurate expanding centre has been fitted to the live spindle of the lathe. This has been found to give better results than loose centres with squared ends for driving. A speed of 80 revs. per min. with from 1/32 to 3/64 feed gives good results in practice. High speed steel ½ in. square is used in Armstrong tool holders. For months past broken high speed tools have been reclaimed by annealing them and forging down to size.

A profile former on the rear of the machine gives the proper contour to the shell. It is so arranged that the pulling in of the tool slide toward the centre of the lathe is done by positive mechanism. Springs have nothing to do with the transverse motion of tool slide when the tool is travelling towards the head stock. When being returned, however, the springs keep it in register with the former. All shells are turned with the carriage travelling toward the head stock of the lathe.

### Inside Profiling

This is done with a solid form tool carried in a special form of bar made of hardened cast steel. The inspector on this machine should see that all shells are profiled between the following weights:—High 28 lbs. 5 ozs.; low 27 lbs. 15 ozs.

### Milling Nose Thread

Milling threads in the nose has to a considerable extent superseded the collapsible tap method. There are machines on the market to day which true up the fuse seat at the same chucking. This machine has two speeds. At the high speed, a lathe tool trues up the fuse seat and when a lever is thrown the machine revolves at low speed and the thread is milled. In this machine the shell is chucked from two points in conical locators one near the tip of the nose and the other at the base. This method gives more accurate and concentric results than when chucked only from the main body of the shell.

### Finishing the Recess and Container Seat

An old nose thread miller was utilized for this operation. Two small milling cutters are placed on the spindle. The cutters are of the following dimensions: 1½ in. dia. x 3/16 in. face and 1 5/16 in. dia. x ¼ in. face. Stops are provided for the machine and the larger cutter mills the recess below the thread while the smaller cutter mills the container seat to size. No hand tapping, no hand reaming nor trueing of fuse seat by hand is necessary to enable shells to pass the shop or government examiners.

FIG. 4. WEIGHTS WORKED TO ON MK. VII SHELLS

### Facing Base to Weight

The rivetted base plate is used and great care is used in facing metal from the base of the shell. Roughly speaking 1/64 in. removed from the base of a shell removes one ounce. The base is faced in for a distance of ½ in. from the outside at that point where, (if it were faced square all the way across) it would leave the shell weighing between the limits:—high 27 lbs. 15 ozs., low 27 lbs. 10 ozs. The number of sixty-fourths removed are calculated from the rule stated above, after shell has been weighed. It has been the practice to bring the shell through shop to this stage with an excess thickness of metal in the base and an excess length. As there is approximately one quarter of inch between gauge limits the weight can easily be adjusted here.

### Machining Recess in Base

The roughing out of metal for the base recess has been accomplished in rather a unique and simple way. High speed steel 1½ x ¾ in. is used. This is cut on a bias so as to have a cutting edge of 1 9/16 in. as shown in illustration. The steel is held in a rigid tool holder. A special jointed bar is placed in the tail spindle which enables the tool to be fed into the work easily as a large handwheel has been placed on the end of the tail spindle. As high as sixteen and seventeen shells an hour have been turned out from this lathe over an extended period of ten hours. With proper clearance and rake on the tool the machine, which is driven by a 3½ in. belt, handles the work easily. The jointed bar allows the carriage to be pulled back quickly as the shell can be removed from the chuck without moving the tailstock.

The recess is then trued up in another machine to the proper diameter and is

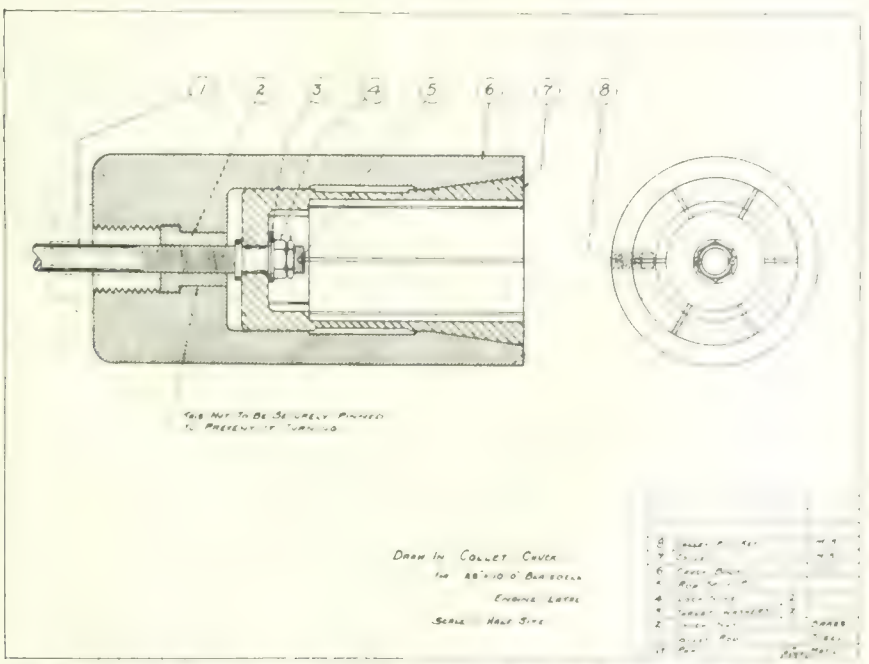

FIG. 5. SIMPLE COLLET CHUCK USED FOR 4.5 SHELLS MK. VII AND MK. IX. THIS TYPE OF CHUCK USED ON HOLLOW SPINDLE LATHES. TIGHTENED WITH AIR CYLINDER OR HANDWHEEL WITH NUT.

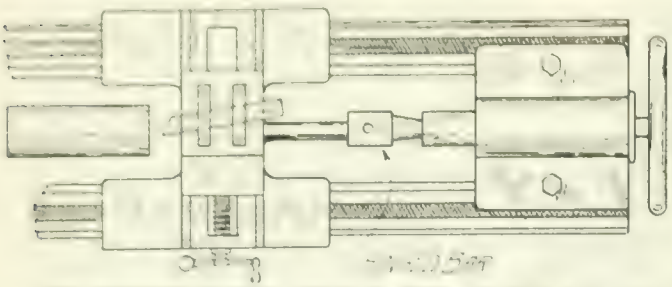
face square across the bottom. A glass finish here makes the riveting of the base plate a more difficult matter than if some tool marks are visible.



ARRANGEMENT OF TAIL SPINDLE WITH JOINTED BAR USED IN RECESSING BASE.

### Machining the Driving Band Groove

This operation has been accomplished in a multitude of ways and seems to present no great difficulties if a careful operator is chosen. Eighteen to twenty shells an hour are common records for a sustained output of ten hours.

### Cleaning Interior for Inspection

A very rapid and efficient method of cleaning the interior of shells and removing all traces of the cutting compound is to place a loop of leather on the end of steel spindle which is driven at about 1,000 revs. per min. Place in the shell a handful of dry abrasive sand, preferably a silica sand, push the shell up to the spindle allowing same to enter the shell. A little carriage on rollers running on a track is necessary. Then start the spindle in motion and the leather will give the interior of the shell a good polishing, centrifugal force throwing it against the formed wall of the shell.

Blasting with steel shot is the final cleaning operation. This chilled steel shot is preferable to sand blasting because it is dustless, or practically so, and can be done anywhere in the shop.

### Succeeding Operations

Pressing bands should be done before the base plate is rivetted. Rivetting base plates and turning bands follow in the succeeding operations. These present no difficulties to the machinist neither does the simple operation of putting the three slots in the nose.

### Varnishing

Cleanliness is the slogan for this operation. It is useless to try to get results in the open shop. A separate, dust proof room is essential. As air drying varnish is not permitted in Canadian shells a baking oven is required. An electric oven is best suited to the purpose for obtaining uniform results.

Just previous to the entry into the varnish room or immediately afterward, a good practice is to wash the shell out with a turpentine substitute such as terpol. Then wipe thoroughly with rags free from "lint." Varnish gives a more uniform covering if poured into the shell through a fine muslin strainer and then drained out again. This method insures against all brushing trouble and patent spray troubles. It takes a little longer but it is a "safety first" practice. An excellent method of preventing varnish from entering the threads and recess of the nose is to get some thin sheet rubber packing and make packing washers. Place these little washers in the recess, below the thread. From 2 in. dia. boiler tubes make thimbles as illustrated. Screw the thimbles down into the shell and have them nip tightly against the washer. This absolutely protects the thread and recess from varnish. The rubber washers are only used once. The thimbles are used over and over again. After each baking the thimbles are put in a hot solution of lye which removes all traces of varnish and leaves them clean for the next heating. A clean transparent coating is required. The proper results can be obtained if a good grade of two hour copal baking varnish is used and it is watched carefully and kept strained; regular practice being to bring the oven up to about 350 deg. F. and keep it there for one hour and a half. Different grades of varnish require different treatment.

### General Practices

Shop inspection is vital. It should be so organized as to look over every shell from every machine. When a machine gets a trifle out of adjustment the first shell that comes off wrong should be caught and the machine adjusted. If six shells a day have to be repaired, it will pay a good share of an inspector's wages. Inspectors keep the quality of the product up and if the shop is balanced it maintains that balance. It enables a firm to make a quicker turnover on the money invested in wages. All shells which can be repaired and salvaged with nose sockets and other means should be taken care of as they accumulate. The loss in allowing them to stand over is greater than most executives realize.

The collet chuck has proved its superiority over all others. It can stand up day in and day out. In hollow spindle lathes a rod and nut with a handwheel at the outer end is a common method of tightening. An air cylinder is used to advantage on short operations where frequent chucking is necessary. A nut on the front of the chuck can be used to advantage on solid spindle machines.

Base plate operations do not give much trouble as a rule. The face of a base plate may have fins removed and the face trued up smooth by placing a hardwood face plate on a small speed lathe, and glued to the face plate a sheet of emery cloth No. 2½. About a twelve inch face plate is a good size. Press the base plate against this when in motion and the results will be surprising if the face plate has been planed true.

Soluble oil gives quite as good results as the expensive paste preparations. Any good reliable oil company can deliver a good grade of soluble oil.

## BLACK SEA—BALTIC CANAL PROJECTED BY CENTRAL POWERS

By Mark Meredith

THE importance of inland waterways is appreciated in all countries where cheap transportation is an absolute necessity, and the latest project in this line that will be carried out is the construction of a chain of canals to connect the Austro-Hungarian rivers with the Vistula and the Elbe to form a great inland waterway system, with the Baltic for an outlet. By this Hamburg will be in touch with Vienna, Bulgarian and Roumanian points, and with the Black Sea, giving the enterprise stategical as well as commercial value.

A glance at the map of Hungary shows how much of the most navigable portion of the Danube flows through that country and no other waterway in Europe is so suitable for large steamer traffic. Obviously, too, there are great advantages in quick conveyance between Silesia, with its mines and industries, and Vienna, and between the Austrian capital, and the coal fields and tin mines of Bohemia.

The project contemplated provides for a canal for large vessels, branching off from the Danube at Ganserndorf, going north-west to Pardubitz, Bohemia, and north-east through the Silesian mining and industrial districts to Oderberg. Another canal will connect the Danube above Vienna with Budweis and Bohemia, and join the Moldau River and a subsidiary waterway will branch off at Manrisch-Ostrau, Moravia, connecting with the Vistula and leading to Cracow. Work is also now in progress on canalizing the Elbe between Meinik, Bohemia, and Jaromir for ships of 600 tons.

It is calculated that freight could be shipped by these inland waterways from Cologne to the centre of the Balkans a distance of 1,560 miles at 8/- per ton. With a Rhine-Danube Canal goods could be conveyed from Germany to Turkey much more cheaply than now, and such a waterway would make the Central Powers much more independent of British sea power, which is perhaps the prime reason why such a costly undertaking is being pushed now.

## MUNITIONS EXPENDITURE FOR 1918

A MINIMUM expenditure of $360,000,000 in the coming year is planned by the Imperial Munitions Board. This outlay will be on the basis of thirty million a month, and it is quite possible that it will be materially increased. In any event, the munitions industry will be maintained.

Of the present monthly outlay of thirty millions, twenty-five millions, by way of Imperial credits, are furnished by the Canadian Government and five millions by the United States in respect of materials purchased there, but entering into the production of Canadian munitions.

A hundred thousand 4.5 shells and a hundred thousand shrapnel are now being turned out monthly. In the near future the latter will be notably increased. The munitions business has long since been down to a permanent working basis. The extent of the orders varies from time to time, but at least the average monthly outlay on the basis above indicated is assured of maintenance in the new year.

## STEEL RAIL SUPPLY IS INSUFFICIENT

AN important conference was held last Thursday at Ottawa at which were present representatives of the railway companies, Imperial Munitions Board and the steel companies. The steel supply is proving inadequate to meet the increasing demand for munition work and steel rails, while the steel companies are being worked to their full capacity. On the new Government railway system, the Canadian Northern, there will be required at least five hundred miles of heavy rails on the main line. This would release enough light rails for the graded extensions and similar trackage. The other roads, including the C. P. R., Grand Trunk and the Intercolonial, all require rails. It is believed that the Government will take action at once to increase the capacity of the rolling mills in connection with the steel plants to meet the essential requirements of the transportation companies without interfering with the production of steel for munitions and other requisites.

## CANADA WILL BUILD CARGO STEAMERS

HON. C. C. BALLANTYNE, Minister of Marine, announced last Thursday that it is the policy of the Government to utilize to the fullest capacity the shipyards of Canada in producing modern cargo steamers of the most approved type for the use of the Government and for registry in Canada. The production capacity of these yards at present engaged in the construction of ships for the British Government, local interests and for foreign account is estimated at from 275,000 to 300,000 tons annually. No more building for foreign registry will be permitted.

The naval constructors' branch is now engaged in developing details of this programme. One type will comprise vessels of 3,000 tons. They will be built on the Great Lakes. Another will be from 8,000 to 10,000 tons.

For the present existing shipbuilding yards will be utilized. These include Vickers' at Montreal, the Geo. DaviesCo. at Levis, the Polson Iron Works at Toronto, the Collingwood Shipbuilding Co., the Port Arthur Drydock Co., and the yards on the Pacific coast. Ships already contracted for by the Imperial Munitions Board and now under construction for Great Britain will be completed. Thereafter Canada will build for Canada and for nobody else. The capacity of the yards is estimated at 300,000 tons per year. This will be increased by careful and economical distribution of labor.

## FORECASTS WAR TRADE BOARD FOR CANADA

A War Trade Board for Canada to deal with industrial relations with the United States in view of coal, steel and other raw material difficulties and embargoes is forecast by the *Financial Post*, which adds:

"This body, which is now being organized at Ottawa, will look after the question of trade between Canada and the United States. F. C. T. O'Hara, who we believe has not been able to handle the situation with the curtailed powers of Deputy Minister of Trade and Commerce, will probably be made chairman. On the board there will be representatives from the Customs Department, the Industrial and Scientific Research Council, Food Controller's office, etc., and also, likely, trade experts from the Manufacturers' Association. The board will co-ordinate the work of issuing licenses and try to work system out of the present confusion over the question of shipments between Canada and the States.

## EMBARGO REMOVED ON METAL ALLOYS

THE Dominion Government has decided for the present and until further notice to permit under license the free export of the metals molybdenum and tungsten, their ores, concentrates, alloys and chemical salts to approved consignees in the United States and France. This will relieve the situation that has been considered somewhat oppressive to Canadian producers.

Since an embargo was placed on the export of these metals the market for the Canadian production has been confined very largely to purchases made on account of the British Government at fixed prices. These fixed prices have been lower, at times considerably lower, than the open market prices offered in the United States and France.

The requirements of the British Government are being met and Canadian producers will now be permitted to take full advantage of the open markets in the United States and France.

It will be necessary for the exporter, previous to shipment, to obtain from the Commissioner of Customs at Ottawa a license to export, and in the case of exports to the United States, it will be necessary under the United States regulations for the shipper or the consignee to obtain from the Bureau of Imports, War Trade Board, Bond Building, Washington, a license permitting the importation of the shipment into the United States.

## SHIPBUILDING PROGRAM IN U. S.

PLANS for a $2,000,000,000 Government shipbuilding programme were revealed at Washington on Friday when the Shipping Board asked Congress for authority to place $701,000,000 worth of additional ship contracts. At the same time an immediate appropriation of $82,000,000 was asked for the extension of shipyards and for providing housing facilities for workmen.

Thus far the board has been authorized to spend for shipbuilding $1,234,000,000, contracts for most of which have been awarded. To-day's request for a further authorization and an additional appropriation brings the estimates of funds needed for shipbuilding to $2,018,000,000. If the additional funds are made available they will be put largely into fabricated steel ship contracts, although some contracts for ordinary steel ships will be let, as will a few for wooden ships on the Pacific Coast.

No new shipyards are planned by the board. The fabricating yards have contracts for about 500 ships now, which will keep them constantly employed into 1919, but the board is anxious to place more contracts and begin on the task of providing materials.

The board's housing plans call for the expenditure of about $35,000,000. The remainder of the $82,000,000 asked for will be used to expand shipyards already built.

# Sidelights on Some United States War Activities

Special Correspondence

*Distinctive traits and characteristics betray themselves in the actions of nations as in individuals. Standardization is pre-eminently an American qualification, and its value as a contributing factor in commerce is being doubly proven by its adoption wherever possible in war. Other distinctive happenings are included in this interesting resume of present conditions across the line.*

EVERY business man knows the importance and the significance of standardization. The word ranks second only to efficiency. It denotes the realization of modern business that waste must be eliminated — the kind of waste that produces the same article a dozen different ways and makes repairs and replacements a matter of tremendous difficulty.

With reference to standardization in peace time opinions are not unanimous. Some do not favor it entirely. They feel that competition in design and variety in process of manufacture are healthy factors in trade and the means of satisfying the widely divergent tastes of the public. Some feel that in certain lines of goods there will never be possible a very rigid measure of standardization. Others, again, favor the most complete degree of standardization all through. They would have uniformity enforced by law in as many lines as conditions would permit. All agree that in many things standardization is very necessary and very beneficial.

With regard to war there can be no question whatever, no difference of opinion. Standardization of supplies is as necessary as discipline in the ranks. Bullets must be made the same to a ten-thousandth part of an inch, rifles must be turned out absolutely to a model; guns, aeroplanes, motor trucks, gas helmets, everything used in the deadly business of war must adhere to set standards. This is the theory of war, at least; it is not always the practice.

### The Moral of the Motor Truck

A young American engineer returned to the United States as soon after President Wilson's declaration of war as the limits of space and the handicaps of travelling out of France would permit. He had been serving with the French army in the engineering branch of the service for a couple of years, but got permission to return home as soon as his own country entered the war. In offering his services to *La Belle France* he had hoped, or at any rate expected, to assist in some of the more spectacular phases of war time engineering. It had developed, however, that he was on most intimate terms with the workings and the parts of motor trucks. No one was more capable than he in reassembling and doctoring disabled motor lorries. Accordingly he had been put in charge of a large workshop some distance back from the lines, where he worked anywhere from fourteen to eighteen hours a day—and saw to it that his staff did the same—at the highly useful if not spectacular business of repairing army trucks.

It was gruelling work in every sense of the word. When a shell lands in the neighborhod of a truck, the result is not hard to imagine. Generally the wreckage is left to rust where it has landed and the Western front is strewn with mangled remnants of wrecked cars. The need for trucks is very great, however, and anything that can be saved must be saved. Accordingly the young American and his staff had to tackle repair jobs that would have made any garage man on this side of the ocean throw up his arms in desperation.

But the great difficulty lay in the matter of duplication of parts. The French army had recruited and conscripted cars and motor trucks from all corners of the earth. There were French cars, English cars, American cars. There were so many different shapes and constructions that the repair depot had to carry no less than 20,000 parts! When a wrecked truck was brought in for treatment, it had to be identified, its origin traced back, its particular make and model determined and then the proper parts found. Necessarily work was slow and the difficulties great.

On his return to the United States, this engineer was a strong advocate of standardization. He had seen the lack of it in its worst phase and, to use an army term, he was "fed up with it." He told of one incident that illustrated effectively the dire results of lack of standardization.

Three motor trucks were parked by the side of a road back of the French line—a big English truck, a French truck of an antiquated model and a converted Ford. A shell landed close enough to scramble the three of them. Only the English truck was left sufficiently intact to be worth bothering with at all, but some of its parts had been scattered about and, when the repair men came to gather that machine together, they struck the job of their lives. There was three of everything in the mass of wreckage.

### Standardizing the Truck

It hardly required the testimony of this officer and others who had had a like experience to convince Uncle Sam of the need for proper standardization. It had already been determined that only one type of truck should be used with the American army.

The means of attaining this end was supplied through the agency of the Advisory Commission of the Council of National Defence. Committees had been appointed to act with the General Munitions Board. The Committee on Army Vehicles consisted of William Butterworth, of Deere & Co., chairman; A. N. Thielaus, Studebaker Corporation; R. V. Bond, Kentucky Wagon Co., and E. E. Parsonage, of the National Implement and Vehicle Association. A committee on Armored Cars had also been appointed consisting of Col. J. H. Rice, of the Ordnance Department of the U.S. Army; Col. C. B. Baker, Quarter-master General, and F. A. Scott, of the General Munitions Board. Finally there was a committee on Automotive Transport, consisting of Karl W. Zimmerschield, of General Motors Co., Detroit, vice-chairman; Charles Clifton, representing National Automobile Chamber of Commerce; C. W. Stiger, representing motor and accessory manufacturers; H. L. Horning, representing tractor interests; Henry R. Sutphen, representing watercraft interests; Frank H. Russell, representing Aviation Engine Association of America; Coker F. Clarkson, secretary and general manager of Society of Automotive Engineers; T. W. Henderson, Henderson Motorcycle Co., Detroit, Mich.

The task of standardizing motor trucks for army use was in its various phases turned over to these committees of business men. The ultimate result was one of the miracles of manufacture that the war has brought about.

### Engineers in Conference

The coöperation of all the manufacturers was first obtained. It was a very earnest evidence of coöperation that was demanded of them. They were asked to "go the limit," to throw in everything they knew to help in the planning construction of the perfect motor truck. They agreed.

New Government buildings in course of construction at Washington, D.C.

The concluding phase of the proceedings was when there gathered at Washington the head engineers of all the big manufacturers. They were collected together in one room, provided with plenty of material for the preparation of plans and then told to "go to it." It was impressed upon them that the country needed a truck as near perfect as was possible under existing conditions and that it was a patriotic duty with each and every one of them to help toward that end without a shade of reservation.

The story goes that the door was actually locked on them. This may or may not be true. But it is a fact that the conference brought forth wonderful results once they got down to work.

Imagine the situation; a score or more of jealous engineers who for years had been feverishly striving to excel each other in the improvement of truck construction. Each man there had shop secrets, exclusive processes, ideas that had been guarded as more sacred than the secret of the Sphinx; and they were asked to coöperate in the production of a perfect truck!

It did not take long for the ice to thaw. First one man laid a shop secret on the table, then another uncorked a hoarded kink and a third explained the nature of a projected improvement. In an hour all the cards were on the table and the group were up to their ears in details and specifications.

To-day every truck manufacturer has handed over to his rivals what was once supposed to be his chief stock in trade—his secrets of construction. But a truck is being produced for the use of the American army that will be as near perfect as it is possible to go to-day—a truck containing just one thousand parts where nearly two thousand were needed before. Every truck that goes to France will be of that model.

Activities incident to the war, have made enlarged quarters imperative.

The repair depots behind the American lines will carry one thousand parts only.

### The Liberty Motor

The same story could be told with reference to the standardizing of the motor used for aeroplanes. It is, of course, generally known that the worth of a flying machine lies in the heart that drives it—speed, durability, facility, all depend upon the humming little mechanism in the nose of the machine. As the United States has felt, and perhaps rightly, that the only road to Berlin is one that cuts through the clouds—in other words, that the war can best be won in the air—the need for the finest motor possible was early recognized:

The same procedure was followed. The coöperation of the manufacturers was sought and obtained, the engineers were summoned to Washington and put into a room with the same instructions, "Evolve us a perfect motor." There was the same letting down of the bars, the same surrender of cherished secrets, the same mutual discussion of specifications and details.

The result was the Liberty motor. American aeroplanes will fly over the enemy lines with the assurance that the motive power throbbing in them comes from a motor that has all the good points American makers know and none of the faults they have been able to find and correct—a hundred per cent. machine as far as present knowledge goes.

### In All Lines Now

The same idea is being carried through in all lines included within the needs of war. The army and the navy demand uniformity, absolute standardization, and Uncle Sam is putting the issue up to the business men of the country. On them is devolving the task of cutting straight roads through the rough hills of competitive construction. And the business men are living up to their task.

Reference has previously been made to waterproofing, as a line in which there was much mystery and mutual secrecy. Manufacturers jealously guarded their methods and processes from their competitors. Standardization for army purposes is being effected, however. Through the mutual efforts of the manufacturers the best methods are being determined for the waterproofing of clothing, tents, coverings, etc.

This is quoted merely as an evidence of what is going on in practically all lines.

### And Now "Camouflage"

The standardization idea is being carried to all extremes and is being made to apply to what may seem the smallest details.

Every now and then a favorite artist drops from the pages of the magazines. His drawings are no longer seen and the public wonders what has become of him. In all such cases the answer is that he has gone into the service of the army. He is being employed on the devising and perfecting of "camouflage."

The war has coined many new words and phrases, but perhaps none more expressive or widely used than "camouflage," the art of concealment. The airship has provided the enemy with a far-reaching, all observing eye and it has become necessary to disguise batteries, hide roads and camps, cover "ammunition dumps" and, in fact, so change the appearance of everything the aerial observer can see that he will be deceived. The work must be well done, for the aerial observer uses a camera—and it is hard to deceive a camera!

With great thoroughness Uncle Sam is working on the standardization of camouflage. Hundreds of artists have been conscripted into the service and are being used in devising and preparing methods of disguise. They are attached to the various camps and the results that they obtain are duly reported. Information is exchanged among the various camps. Even this seemingly small phase of warfare is being worked out on a basis of absolute standardization.

The moral of it all is that the U.S. Government is obtaining tremendous results in the matter of standardization because the coördination of business men has been obtained. In no other way could the Liberty motor have been evolved. The system of national committees is making it possible to organize any industry to the point where anything needed for war purposes can be obtained.

Standardization is a matter for business men to handle and Uncle Sam has had the good, common sense to delegate it to business men.

And the results prove the wisdom of this course.

## HOW A SCREW MACHINE JOB WAS DONE

By H. Middletown

WE had to turn out a quantity of the rods shown in the drawing. They were easy to make but at the time the only machine available was a ⅜ in. Hartford automatic which was suitable for work only 1½ in. in length. That was sufficient for the portion to be turned and it was by stretching things a little increased to feed 1¾ in. The stock was then arranged to feed out 1 9 16 in. for the first operation of turning and then to feed the remaining 1¾ in. for the necking and cutting off operations. Two stock stops were used in the turret and the box milling tool located between them to provide the proper sequence of operations. The fourth hole in the turret head was left vacant.

As is apt to be the case when working near the limit, an interference occurred and in an unexpected quarter. It was found that on bringing back the turret after the turning operation the turret would start to index before the box tool had cleared the work. This was

was enough to clear the tool while it swung by, this to be followed by feeding up to the stop as before. This simple little trick solved the problem and the job was run satisfactorily.

## SHIPBUILDING PROGRESS IN B. C.

EVERY shipyard in British Columbia [illegible] for the Imperial Munitions Board is well ahead of its schedule, according to E. C. Walsh, who is the official responsible for the launching into the water, and whose supervision is one of the most important under the Munitions Board. The building of these twenty-seven steamers has meant a great deal for the lumbering industry of the province, for about 1,400,000 feet of timber is needed for each ship, and ten million feet has yet to be delivered. Not only are old-established logging camps engaged on getting out ship timber, but four new camps have been started for this purpose. Merrill & King, on Thurlow Island, get out 100,000 feet a day, and a similar quantity is logged on Thurlow Island at the P. D. Anderson camp. The Hansen camp at Granite Bay is getting out 100,000 feet, and so does the Jackson Bay camp, which is a Munitions Board plant, operated by the Colonial Trust Co. The needs of the shipping has resulted in lumbermen getting out the long lengths necessary for the programme, and the production of ship knees is also a big feature. These knees are very essential in order to give the requisite strength to the vessels, and the fleet now under construction will be a big advertisement for British Columbia timber.

### Lumber Inspected

The lumber is very carefully inspected and it must come up to a grading set by Mr. Walsh, who was with the Hastings mill for twenty-five years. The Inspectors' Bureau Association also checks up the quality and issues a certificate if it comes up to grade, and there is a representative at every mill cutting timber for the ships. The shipyards are also held responsible for what they receive, so there is small chance of faulty lumber going into the vessels.

At the Western Canada Shipyards, of which W. W. Clark is superintendent, there are four ways. Number One hull is completed and should be launched at any time, but she was finished so far ahead of the scheduled time, which was February 1, that the shafting and other engine room gear has not arrived. Otherwise she could be sent into the water. When it is considered that the ground for the yard was broken as recently as June 5, it will be seen that rapid work has been done. Work on the second vessel will be about 20 per cent. faster than on the first ship as the workmen get more efficient and more men are trained. The ceiling has been started on the third vessel, and the fourth is in frame, while the saws are whining on the lumber for the fifth.

False Creek is beginning to look like a miniature Clyde, for right across from the Western Canada yard is the big Coughlan plant, where steel steamers are under construction and the hull of one is looming large, for she will be [illegible] this month.

### Launching Dates

The launching dates set for the six ships at the Western Canada yard are: Feb. 1, March 15, April 21, May 15, June 7, and June 13. The dates at Lyall's yard, North Vancouver, are: Jan. 20, Feb. 10, March 2, March 23 and April 11. The Cameron-Genoa, Victoria, launching dates are: Feb. 1, March 1, April 1 and May 1. The Foundation yard, Victoria, dates are: Jan. 20, Feb. 20, March 20 and May 20. The dates for the New Westminster Construction and Engineering Co. are: Feb. 1, March 1, May 15 and June 15, and for the Pacific Construction Co., Coquitlam, March 1 and May 1.

All the yards engaged in the work have been fortunate in that no labor troubles have interfered with the progress, and Mr. Walsh states that the greatest harmony has prevailed, all hands apparently realizing the need for turning out the tonnage as rapidly as possible. This feeling is prevalent from the logger who drops the trees to the men who build the ship, and the six yards are working in a spirit of friendly rivalry.

The steamers under construction are 250 feet long, 43½ feet beam, and a moulded depth of 25 feet. They will carry 2,800 tons deadweight on a draught of 21 feet, and most of the lumber used in construction is Douglas fir.

### Are Strong Vessels

A visit to the Western Canada yard shows that the specifications of the Imperial Munitions Board are high. From the vessel in frame to the completed No. 1 hull every timber seems to be of beautiful lumber of immense strength, and the vessels are very solidly built. There is no evidence of any weakness, and the magnificent timbers are a great testimony to British Columbia's great lumbering asset. The ships are to be built to Lloyd's A1 classification and the British Board of Trade's requirements for cargo steamers.

The frames, of course, vary in size. Some are as big as 21 x 23 inches, and the smallest is 12 x 14 inches. The rudder-post is 37 feet long and 20 x 20 inches, and is in one piece, as is the propeller post, which is 30 x 36 inches and 37 feet long. The beams are 14 x 12 and 14 x 13, and the stem is in one piece, 45 feet long and 18 x 26 inches.

It will be seen from the few instances quoted that strength is insisted on, and there is no reason to fear that this British Columbia fleet built of B. C. lumber will bring discredit on the province.

## BRITAIN'S HIGH SPEED STEEL MARKET

"The Ironmonger," London, in a recent issue expresses concern regarding Great Britain's future market for high-speed steel. It is stated that in the last three years many countries have been forced to provide themselves with products formerly imported. In its editorial columns "The Ironmonger" comments on the situation as follows:

"Until the outbreak of war, Sheffield was doing a lucrative export trade to the United States, Germany, Japan, and other markets in high-speed steel and the more expensive varieties of carbon crucible steel. This has been practically extinguished by prohibition of exports, and the manufacturers concerned fear that the chances of its recovery are not very encouraging. Recent inquiries in the United States as to the position of the high-speed steel supply and the desirability of relaxing the regulations prohibiting export to that country have elicited the emphatic reply that the American engineers are now able to get all they need, which means that the Sheffield article is no longer indispensable to them. It is evident, therefore, that the American tool-steel makers have made considerable advances both in output and in the quality of their product, since the consumption is now much greater than at any previous time. Sheffield's German connection in the same kind of material has, of course, gone, and if the American trade suffers a like fate, the cutting off of these two valuable markets will represent a serious loss to our manufacturers. Our trade with Japan is affected in the same way. The development of Japanese engineering and shipbuilding brings with it a large and progressive consumption of best tool and other steels, which in the past have been supplied mainly from Britain, but such commodities are now produced in the country itself. Fortunately for our manufacturers the Japanese steel of this class is not of really good quality, and the Japanese Government still continues to employ the British product."

## STORING COAL IN BULK

WHEN coal is stored in bulk the piles should not be higher than 10 ft. according to the British Fire Prevention Committee. Iron pipes 3-in. or 4-in. in diameter, or, failing these, eathenware pipes or ducts formed of incombustible material, should be inserted vertically in the piles as they are built up, their lower ends being at different heights above the ground throughout the piles, with about one pipe or duct to every 300 sq. ft. of surface; a thermometer should be occasionally lowered down these pipes or ducts to ascertain the temperature from the centre of the pile; and if wet, very small, soft, or impure coal is received it should be dumped round the edges of the pile, or in some position where the air can get to it freely and where other coal will not be packed on top of it.

SOME years ago molybdenum looked very promising as an alloy in tool steel, but unfortunately it was found that while the steel had very often remarkably efficient cutting qualities, it frequently ran with fine hairline seams, and very peculiarly the molybdenum tended to volatilize out of the surface of the steel on heat treatment. Also in magnet steel it has not proved as satisfactory as tungsten. Metallurgically considered molybdenum should have about twice the efficiency of tungsten.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

## DOING SMALL JOBS SIMPLY AND ECONOMICALLY

By H. Middleton

THE four jobs described in detail below were not of an unusual nature in any particular respect, but were successfully performed with simplicity of method and small outlay.

### To Prevent Slipping in Sensitive Drill Chucks

The average drill chuck in use on sensitive machines is extremely hard on the shanks of drills. Should there be the slightest doubt of this, an examination of the drills under ½ inch in any shop will remove it at once. The "Hartford" drill chuck, Fig. 1, is typical of a class of stronger chucks which ought to hold any drill without shipping but which the youth of to-day can beat a mile. Give him a new drill and some holes to put through one inch steel plates and he will have the drill turning around in the chuck in the first twenty minutes. The driver shown is nothing but a piece of round steel slotted to fit loosely over the projecting jaws of the chuck and having two tightly fitted set screws that run into the flutes of the drill but it effectually prevents slipping and scoring the shanks and we find it a time saver on all quantity work.

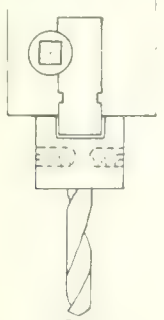

FIG. 1.

### Turning With Swiss Files

We had three or four thousand of the pins shown in Fig. 2 that were made on the screw machine and on which the journals had to be brought closer than was possible in that machine. As turned out the journals ran from 0.156 to 0.157½ and the proposition was to reduce the larger ones to the former size.

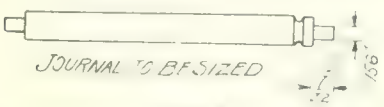

FIG. 2.

The short length, the sharp corner, and the small amount to come off made it look like a difficult job of turning. But it was easily and quickly done by filing, holding the pieces in a good chuck and using 4 in. American Swiss files, No. 2 cut. Being only ¼ in. wide, the workman could feel the file resting flat on the piece and having a safe edge and full teeth right up to that edge it was

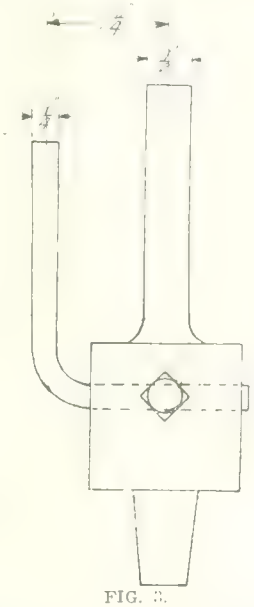

FIG. 3.

comparatively easy to do perfect work, impossible with big files.

### Ratchet Drilling Large Holes

Down at the nail factory they wanted to get four large holes put through the frame of a hammer they were setting up but there was as yet no power of any sort in the building. To make a hard job easy, we ratchet drilled one half inch pilot holes through first and by the time that was done had made up the sweep tool that is shown in Fig. 3. The tool requires no explanation, suffice it to say that the blade, of tool steel, was strong enough for the work if not fed too fast and that rate of feed was fast enough to suit a white man and the result was a nice job in a reasonable time.

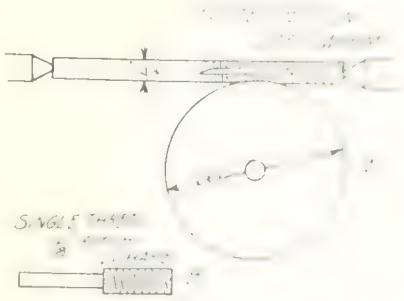

FIG. 4.

### Hobbing a Small Worm Gear in a Job Shop

A mechanical engineer needed a small worm and gear for an experiment and took the job to a nearby shop with a suggested method without the use of special tools. The details of both members are given in Fig. 4. The method as outlined produced a most satisfactory piece of work.

Though only soft steel was required, the worm was made of tool steel and a longer piece was threaded than was needed at the finish. This is shown at A where the worm is mounted on the centers. In the extra threaded part, teeth were cut which formed a hob that answered to cut the gear. As the gear was ordinary bar brass, the unhardened steel hob cut it fairly well and a sufficient length of the latter was provided to shift along and present a sharp face for the final sizing. After the gear was cut, the stem was turned off and the rest of the tool steel thrown away. The work was done with a pair of plain centers in a hand milling machine.

## THREADING PIPE FITTINGS ON A HARTFORD AUTOMATIC

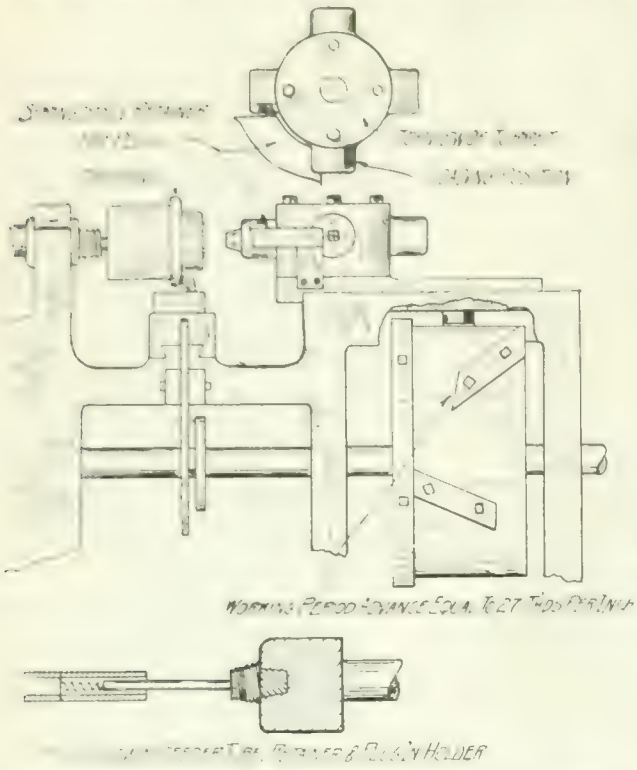
By Donald C. Hampson

THE automatic screw machine would not ordinarily be the proper tool on which to thread pipe fittings, but in one case it proved to be all that could be asked. The fittings were ⅛-inch square head plugs of cast iron—the kind commonly retailed for a couple of cents. The making of pipe fittings has been carried on by specialists and developed until it seems as if further methods of manufacture would not result in any marked saving. However the experiment as instanced in the automatic screw machine herewith described proved successful in all respects.

Reference to the drawing shows that complicated parts, springs, dirt collecting spot, etc., were eliminated in the design. The work holders are tool steel pieces with a square hole in one end, which end is hardened. An opening die is used and after it has been run over the plug the right length, it is tripped and the turret recedes which might give the plug a chance to fall or catch in the die but for a rod actuated by the feeding mechanism which advances and holds the plug upright until the turret clears sufficiently. The plugs are ejected by the centrifugal force of the revolving turret. In place of a trip lever on the outside of the die head, a ring has been provided that permits the chasers to be opened at any part of the revolution and to perform this the cross slide movement is employed to bring up a pusher against the ring. The normal move-

[illegible] place of expensive and complicated devices to accomplish the same results.

The die, of course, has no movement other than that of revolving, the plug being carried up to it and back. As even the most carefully made castings vary a trifle and in threading the die must pass over and beyond the round part to



SKETCH SHOWING CAM ARRANGEMENT FOR AUTOMATIC OPERATION.

ticularly as it has been found necessary to set an eighth of an inch as the safe maximum length for a grip on the plug at the moment of die opening. To keep the die and the holders at a safe distance, the turret is allowed to advance so the distance between these parts is ⅛-inch and from that point the die draws the plug out of the holder which is quite permissible, as the slight taper on the head cannot turn in the square hole at any point and the real object of setting the head in full length at the start is to bring the plug up central with the dies.

To avoid any possibility of the plug being drawn out of the holder, drawing the turret slide along with it, the turret drum has a "cam" at its forward end that limits the travel of the roller in that direction, this cam taking the form of a band entirely around the drum. Another feature of the camming is found on the turret advance cam which has a portion beveled to give an advance equal to very nearly the lead of the thread to be cut. The idea of this is to start the thread without the use of springs which is possible in the case of pipe threads and with a set up such as this: after the chasers have taken hold, the slight difference between their lead and that of the cam pulls the plug from the holder and there is nothing to jam the die and cause injury.

The running of the machine is entrusted to a boy who sits in front of the machine and puts a plug in each holder as it is indexed to the loading position before him. To retain the plug in the holder as the turret revolves, a clock spring retainer bent to shape is used. The centrifugal force of the turret ejects the plug after threading, throwing it into a box on the rear. Four sets of cams were put on each drum, all of them made of cast iron and used without machining.

Another pipe job done on the automatic was the making of some headless plugs, the same size and shape as the threaded part of the ones mentioned above. In this case the plugs were made of steel. The bars were handled just as any automatic job—the forming tool put on the pipe taper, the die in the turret threaded, and the cut off tool severed the piece. There was no need for the turret to revolve and this was fixed by limiting the travel of the slide so the index and lock were not engaged.

## MANUFACTURE OF HARDENED THREAD GAUGES.—V*

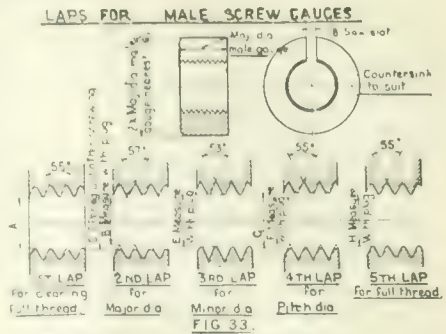
By G. Doorakkers

WE mentioned previously that about .001 in. is left on all diameters for shrinking and lapping allowance for the large and medium sizes, and about .0005 in. for the smaller sizes.

### Laps For Male Screw Gauges

Fig. 33 shows the design of the different types of laps used. They are made of a close-grained cast iron and split after being finished. A collar with a screw or even a carrier will serve for lapping. These laps are made in five different types:—

Lap 1 For all thread (.001 over size.)



LAPS FOR MALE SCREW GAUGES
Countersink to suit
55°
57°
1ST LAP For Clearing full thread
2ND LAP For Major d.o
3RD LAP For Minor d.o
4TH LAP For Pitch dia
5TH LAP For Full Thread.

FIG 33.

Lap 2 –For major diameter.
Lap 3—For minor diameter.
Lap 4—For pitch diameter.
Lap 5—For full thread.

Lap 1.—Lap 1 is used for cleaning the thread all over, and is therefore made .001 larger in all diameters than the finished size of the gauge. It is cut with the circular tool for internal gauges—Fig. 25—and if that tool is set up correctly it should be sufficient to measure dimension A only.

A=(f—1.28064P+.001), where f is the major diameter of the male gauge. This dimension can be measured with a plain plug.

Example.—Dimension A wanted for Lap 1 for a male screw gauge .886 24 RH.

A=.886—.05335+.001=.8336.

Lap 2.—Lap 2 is used for lapping the major diameter only. The lap, therefore, has to clear on the flanks and the core diameter. It is cut with the 57 deg. tool till a plug of diameter B enters tightly.

B f—2x where x can be calculated as follows, in Fig. 35:—

$$X = AC - BC$$

$$AE = \tfrac{1}{2}P$$

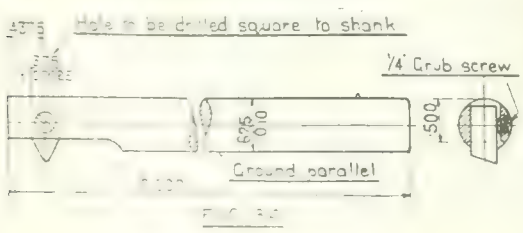
$$AC = \frac{\tfrac{1}{2}P}{2 \tan 28\tfrac{1}{2}\text{ deg.}}$$

$$BC = DC - R = \frac{R}{\text{Sin } 28\tfrac{1}{2}\text{ deg.}} - R$$

$$X = \frac{\tfrac{1}{2}P}{2 \tan 28\tfrac{1}{2}\text{ deg.}} - \frac{R}{\text{Sin } 28\tfrac{1}{2}\text{ deg.}} + R$$

After screwing to dimension B the hole has to be opened out to diameter C as minimum size. C f—(2C—2D) (see Fig. 1)=f—1.32808 P. This dimension C is a minimum and the hole can be opened out slightly larger.

*Contributed to a recent number of The Engineer. No. 4 appeared Dec. 13.



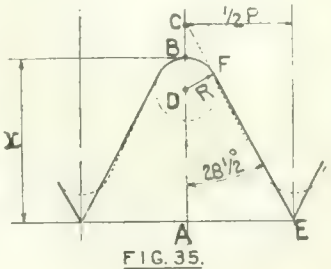


FIG. 35.

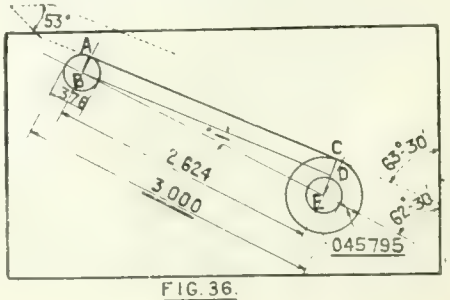

FIG. 36.

Example.—Wanted dimensions B and C for lap for major diameter for male screw gauge .886—24 RH.

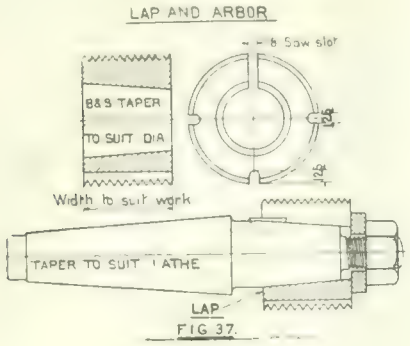

FIG 37.

$$B = .886 - \frac{.04166}{\tan 28\frac{1}{2}\text{ deg.}} - \frac{.82182}{\sin 28\frac{1}{2}\text{ deg.}} + .011442$$

$$= .886 - .06418 = .82182$$

$$C = .886 - 1.132808P = .886 - .040012 = .846$$

Lap 3.—Lap 3 is used for lapping the minor diameter only. It is cut with the circular tool for internal gauges—Fig. 25—to dimension E. This dimension can again be measured with a plain plug.

$$E = f - 1.28064P$$

The flanks are then cut away with a sharp-pointed 53 deg. angle tool. This tool is made in the same way as the master tool and afterwards cut off with an elastic wheel to suit the holder shown in Fig. 34. The angle of the tool is ground on the fixture shown in Fig. 3 by using a packing piece or a bush of a certain thickness between the tool and the bottom peg. The thickness of the packing piece is calculated as follows:

In Fig. 36 AB=.188. The new angle of inclination with the vertical is 63½ deg. BD is a line drawn parallel with AC. BD therefore makes an angle of 1 deg. with the line joining the centres of the peg.

DC = AB

In triangle BDE:

DE = 2.624 × sin 1 deg. = .0457910

EC = DC + DE = .188 + .045791 = .233791

The thickness of the bush or the packing piece is therefore .233791 — .188 = .045791.

Example.—Dimension E wanted for lap for minor diameter for a male screw gauge .886—24 RH.

$$E = .886 - .05335 = .83265$$

Lap 4.—Lap 4 is used for lapping the pitch diameter or the flanks. It is cut with a 55 deg. sharp pointed tool, shortened to suit the holder shown in Fig. 34. With that tool the lap is cut to dimension F.

$$F = f - 1.6008\ P \text{ (see Fig. 1)}$$

The hole is then opened out to G = 1.13282 (see Fig. 1).

Example.—Wanted dimensions F and G for a lap for pitch diameter for a male screw gauge .886—24 RH.

$$F = .886 - .0667 = .8193$$

$$G = .886 - .040012 = .846$$

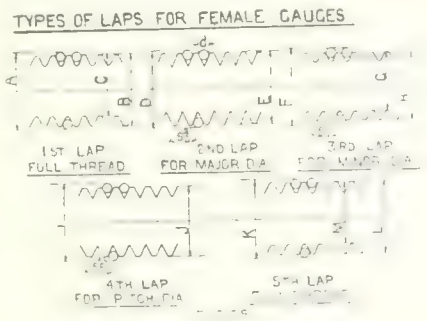
Lap 5.—Lap 5 is used for lapping the entire shape of the thread. It is cut with the circular tool for internal gauges—Fig. 25. Dimension H can be measured with a plain plug.

$$H = f - 1.28064 \text{ (see Fig. 1).}$$

Example.—Wanted, dimension H for a lap for full thread for a male screw gauge .886—24 RH.

$$H = .886 - .05335 = .83265$$

It might be mentioned that good lapping results have been obtained by using carborundum paste for roughing and diamontine for finishing and polishing.



### Laps For Female Gauges

We mentioned before that it is good practice to leave .001 to be lapped out in medium sized female gauges, and about .0005 in the smaller tapped gauges. The laps are made of close grained cast iron, and Fig. 37 shows the cheapest and most effective kind of lap, together with the arbor on which it is mounted. The lap is sawn right through in one place, and the taper hole allows a certain amount of expansion. A Woodruff key prevents the lap turning round on the arbor. The laps are again divided into five types:—

Lap 1—For full thread (.001 under size).
Lap 2—For major diameter.
Lap 3—For minor diameter.
Lap 4—For pitch diameter.
Lap 5—For full thread.

These five types are shown in Fig. 38.

Lap 1.—Lap 1 is cut the correct shape of thread .001 under size. It is cut with a circular form tool—Fig. 18—and is used for cleaning out the thread. The dimension A over the three wires is one thousandth under the dimension over the three wires for the check for pitch diameter or the full thread check. The major and the minor diameters are one thousandth under the major and minor diameter of the finished female gauge. Assume f the major diameter of the female gauge.

$$A = f + \frac{d}{\sin 27\frac{1}{2}\text{ deg.}} + d - 1.6008P - .001.$$

$$B = f - .001.$$

$$C = f - .64032 - .001.$$

Example.—Wanted the dimensions A, B and C for a female screw gauge 1.998—14 RH; d for 14 thread=.040.

$$A = 1.998 + \frac{.040}{.9617486} - .040 - .11434 - .001$$

$$= 2.00928$$

$$B = 1.998 - .001 = 1.997.$$

$$C = 1.998 - .04574 - .001 = 1.95126.$$

Lap 2.—Lap 2 is used for lapping the major diameter of the female gauge only. It is cut with a 53 deg. sharp pointed tool and a standard female radius tool. The 53 deg. tool is manufactured in the same way as the tool for Lap 3 for male gauges, except the length which is not shortened. Dimension E equals the major diameter of the female gauge. Dimension D equals the major diameter of the female screw gauge + 2x, where the value x is calculated as follows:—In Fig. 39, in triangle DBE:

$$DB = \frac{1}{2}P.$$

$$DE = \frac{DB}{\tan 26\frac{1}{2}\text{ deg.}} = \frac{P}{2\tan 26\frac{1}{2}\text{ deg.}}$$

In triangle ABC:

$$AC = R.$$

$$AB = \frac{R}{\sin 26\frac{1}{2}\text{ deg.}}$$

$$DG = AB - R = \frac{R}{\sin 26\frac{1}{2}\text{ deg.}} - R.$$

$$FG = ED - DG = \frac{P}{2\tan 26\frac{1}{2}\text{ deg.}} - \frac{R}{\sin 26\frac{1}{2}\text{ deg.}}$$

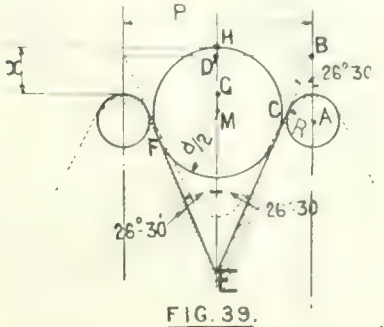


FIG. 39.

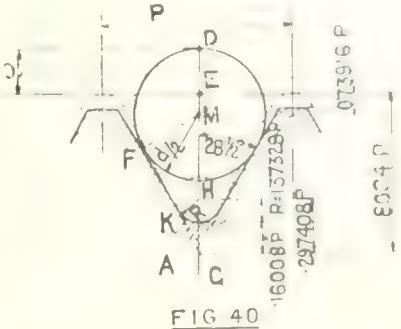

FIG 40

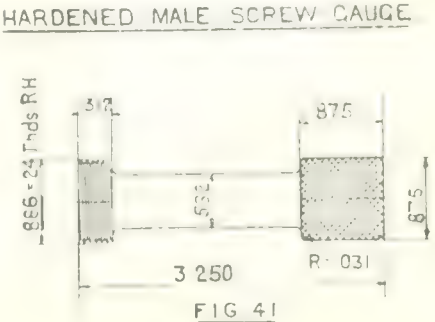

FIG 41

In [illegible] FMF

$$\frac{FM}{MF} = \frac{d}{\text{[illegible]}}$$

[illegible] $= \sin 26^\circ$ [illegible]

$$FH = FM + MH = \frac{d}{2 \sin 26\frac{1}{2} \text{ deg.}} + \frac{d}{2}$$

$$x = FH - FG = \frac{d}{2 \sin 26[illegible] \text{ deg.}} + \frac{d}{2} - \frac{P}{\text{[illegible]}} + R$$

$$2 \text{ [illegible] } 26\frac{1}{2} \text{ deg.} \qquad \sin 26\frac{1}{2} \text{ deg.}$$

rect radius, the same tool which is used for shaping the female radius tool—see Fig. 15. Dimension F over the three wires $= f + 2x$, where $x$ is calculated as follows: In Fig. 40:—

$x = AD - AF$

$AD = AM + DM = AM + \frac{1}{2}d$.

$AF = GE + GH + AH$.

$x = AM + \frac{1}{2}d - GE + GH - AH$

In triangle AMF:

$$AM = \frac{FM}{\sin 28\frac{1}{2} \text{ deg.}} = \frac{d}{2 \sin 28\frac{1}{2} \text{ deg.}}$$

d = .040.

$$x = \frac{.020}{\sin 26\frac{1}{2} \text{ deg.}} + .020 - \frac{.071428}{2 \tan 26\frac{1}{2} \text{ deg.}}$$

$$= \frac{.0098}{\sin 26\frac{1}{2} \text{ deg.}} + .0098$$

$x = .0648232 - (.0716312 - .0219634 + .0098) = 3.00535$

$D = f + 2x = 1.998 + .01070 = 2.0087$.

$E = 1.998$.

Lap 3.—Lap 3 is used for lapping the minor diameter of the gauge. The minor diameter of the lap is therefore

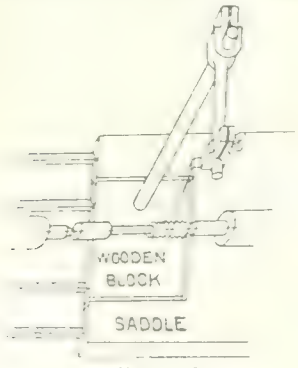

FIG. 43.

the same as the minor diameter of the finished female gauge. It is screwed with a 57 deg. angle tool with the cor-

$GE = .8004$ P (see Fig. 1).

$GH = .297408$ P (see Fig. 1).

In triangle AHK:

$$AH = \frac{R}{\sin 28\frac{1}{2} \text{ deg.}}$$

$$\text{Therefore } x = \frac{d}{2 \sin 28\frac{1}{2} \text{ deg.}} + \frac{1}{2}d - \frac{R}{\sin 28\frac{1}{2} \text{ deg.}}$$

$$.8004 \text{ P} + .287408 \text{ P} - \frac{R}{\sin 28\frac{1}{2} \text{ deg.}}$$

Diameter H is the diameter with the radius cut away.

$H = f - .147832$ P (see Fig. 1).

G [illegible] $f - 2$ D—(C [illegible] D) (see Fig. 1) $f - .71423$ P

Example.—Wanted dimensions F, G and H for a female screw gauge 1.998—14 RH.

$F = 1.998 + 2x$, where $x = .0419148 + .020 - .05717 + .02123 - .02054 = .00543$

$F = 1.998 + .01086 = 2.00886$.

$G = 1.998 - .0510 = 1.9470$.

$H = 1.998 - .0106 = 1.9874$.

Lap 4.—Lap 4 is used for lapping the pitch diameter. It is cut with a 55 deg. sharp pointed tool. Dimension I. over the three wires, is the same as dimension B for check for pitch diameter—see Fig. 32.

$$I = f + 2x, \text{ where } x = \frac{d}{2 \sin 27\frac{1}{2} \text{ deg.}} + \frac{1}{2}d - .8004 \text{ P.}$$

Dimension J equals dimension H for the third lap.

$J = f - .147832$ P.

Example.—Wanted the dimensions I and J for a female screw gauge 1.998—14 RH.

$I = 1.998 + .01228 = 2.01208$.

$J = 1.998 - .0106 = 1.9874$.

Lap 5.—Lap 5 is used for lapping the entire shape of the thread. Dimension K is the same as dimension I for Lap 4, and the minor and major diameters are the same as for the gauge.

Example.—Wanted the dimensions K, L and M for a female screw gauge 1.998—14 RH.

$K = 1.998 + .01228 = 2.01028$.

$L = 1.998$.

$M = 1.998 - .04574 = 1.95226$.

### Hardening Male Screw Gauge

Fig. 41 shows a simple type of a male screw gauge. The same gauge is shown laid out in operations of manufacture in Fig. 42. The operation drawing is practically self-explanatory. It will be seen that the gauge is hard in the threads only, and that the carbon has been turned away everywhere else. In case of thread depth gauges hard faces cannot always be avoided, and have to be put up with. The carbon is turned away to eliminate distortion after hardening.

Remarks.—Operation 5: Rough diameter thread.—The outside diameter is turned to $(f + .020) - .003$, where f is finished outside diameter of gauge, and the value behind the brackets represents the limit of accuracy. The diameter for the gauge in question is therefore $(.886 + .020) - .003 = .906 - .003$.

Operation 6: Rough screwing.—On this operation thread is roughed out to about two-thirds of the depth to obviate a too deep penetration of carbon which would necessitate a long carbonising time.

Operation 16.—Heat up to 800 deg. and cool four times in water. This operation is performed to minimize the stresses and strains after the final hardening.

Operation 18.—Turn or grind thread diameter. The diameter of the thread $= (f + .0025 + a)$ with no limit where a is a shrinking allowance.

$a = .001$ for medium and larger gauges.

$a = .0005$ for the very small sizes.

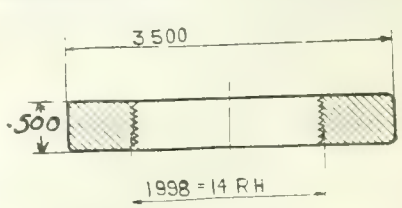

FIG. 44

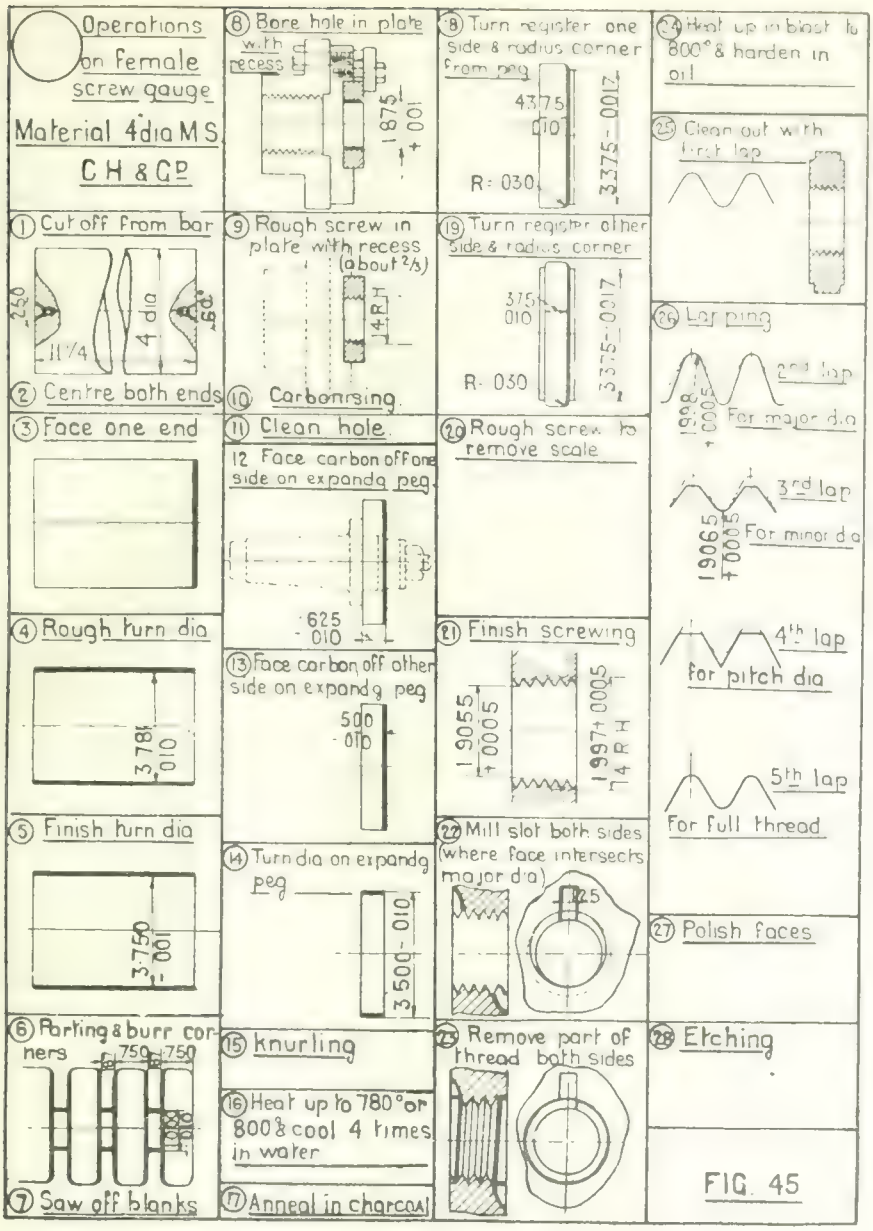
The diameter for the gauge in question is

$.886 + .0025 + .001 = .8895$

Operation 19.—Rough screwing.—The dimension over the three wires is



Operations on Female screw gauge
Material 4 dia M.S.
C H & C P
1 Cut off from bar
2 Centre both ends
3 Face one end
4 Rough turn dia
5 Finish turn dia
6 Parting & burr corners
7 Saw off blanks
8 Bore hole in plate with recess
9 Rough screw in plate with recess (about 2/3)
10 Carbonising
11 Clean hole

FIG. 45

$$(f + a + 2x + .010) - .001, \text{ where } x = \frac{d}{2 \sin 27\frac{1}{2} \text{ deg.}} + \tfrac{1}{2}d - .8004 \text{ P.}$$

d for 24 threads = .025.

x for 24 threads per inch = .006227.

The dimension over the three wires for the gauge in question is (.886 + .001 + .01245 + .010) — .001 = .9095 — .001.

Operation 20.—Finish screwing.—This is, of course, the most important operation. By preference all dimensions should be taken without removing the gauge from the centres. The only dimension that presents difficulties is the dimension over the three wires. This difficulty can be overcome by slipping in the wooden fixture shown in Fig. 43. In that fixture the three wires are suspended on cotton. The wires are fastened to an adjustable arm which can be adjusted at will. When a cut is taken the fixture is removed. The dimension from the top of the thread on one side to the bottom of the thread on the other side is f—.64032 P + .001.

For the gauge in question that dimension is .886—.026675 + .001 = .8603. The dimension is measured with the special micrometer attachment. The dimension over one wire is f + x + .001, which is for our gauge .886 + .00622 + .001 = .8932. The dimension over three wires is f + 2x + .001, which is for our gauge .886 + .01245 + .001 = .89945. The outside diameter is f + .001. For our gauge .887.

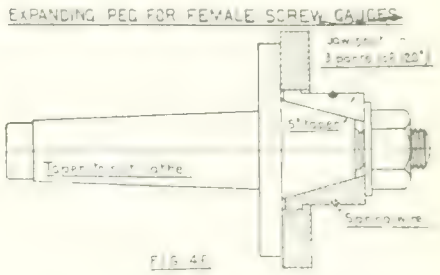
Operations 21 and 22—Mill slot and turn away part thread. These operations are performed to do away with the thin part of the thread, which would easily break off or chip after hardening.

Operation 23.—Heat up in blast and hardren in oil. It was found that the quicker the gauge was brought to its hardening temperature the smaller was the amount of distortion. For the final inspection after lapping the dimension over the three wires can be measured on a similar fixture to that shown in Fig. 43, except that a block has to be added to clamp the work.

### Hardened Female Screw Gauge

Fig. 44 shows the simplest form of a female screw gauge, and Fig. 45 shows the successive operations in making it. It will be seen that the carbon is turned away wherever hardness is not essential.

Remarks.—Operation 8: Bore hole.—For this operation the blanks are held in an adapter plate, and the hole is bored out to (f—1.28064 P—.030) + .001, where f = finished major diameter of gauge, and the value behind the brackets represents the limit of accuracy. For our gauge the diameter of the hole is (1.998 — .09148 — .030) + .001 = 1.877



+ .001. The dimension, being very close to a standard size, was taken as 1.875 + .001.

Operations 12, 13, and 14.—In these operations the carbon is turned from the two faces, and the diameter on an expanding peg shown in Fig. 46.

Operations 18 and 19.—In these operations registers are turned on both sides of the gauge to suit the adapter plate for the finished screwing. The finished screwing is left .001 under size, slots are milled on both sides of the gauge, and the part threaded is turned out for the same reason as stated for the male gauges.

## EACH MAN TO HIS MATERIAL

By D. A. Hampson

THE most famous saying of the late Bob Fitzsimmons was to "strike from where your hand is." The machinist doing work around in various factories cannot help notice that the employees of the various places follow this advice unknowingly. For instance in a large creamery, the writer saw the engineer cutting threads on some pipe and for a lubricant he had a squirt can filled with butter: he was cutting nice threads too—his pipe vise was near the engine and he kept the can resting on the cylinder head where the butter was heated to a liquid.

In a leather tanning plant, they burned leather scraps under a 40 h.p. boiler and while it wasn't coal by any means, it did very well with the aid of a blower. Elsewhere in the plant leather scrap was used—in babbitting, a piece of leather took the place of putty, ends of leather were slitted up into belt laces, etc. Down at the paper mill they worked over vast quantities of old rope into pulp but it was only natural that for repairs and in an emergency rope was used for supports and slings and ties where an outsider would have insisted that iron rods and wood blocks were the only materials that would fill the bill.

## STEAM POWER DEVELOPMENT

A SHORT time ago V. H. Manning, Director of the Bureau of Mines, Department of the Interior, Washington, D.C., made the statement that 25 per cent. of the coal production of the United States was wasted through inefficient use. His point was that a large proportion of the steam engine and boiler plants of the country are not up-to-date and are consuming coal wastefully as compared with results given by plants of the latest and most approved design.

Since engineering methods are always advancing, it is out of the question that all of the power plants of the country should be at any one time of the latest design, but Mr. Manning's statement is very suggestive as to the importance to the country of improvements in its power equipment. The annual production of coal in the United States is now about 600,000,000 tons, and 150,000,000 tons of this would be saved if all consuming plants were as good as those of the best type. Perhaps the most impressive idea of this saving can be obtained if the reader will think of the labor involved in mining, handling, and transporting 150,000,000 tons of coal, and of shoveling it into the fire-boxes; and of the benefits that might be derived by having that labor distributed in the other industries.

### Generation Back Comparison

If it is interesting to calculate the savings that may be effected in the future by bringing all equipment up to the standard of what at this date is recognized as the best, it is also interesting to compare not only the best practice but the common practice of to-day with the best practice of a generation ago. Mr. Manning's statement has led us to make an inquiry along this line, says a statement issued by the National City Bank, New York, and looking backward for a starting point we fixed upon the Centennial Exhibition at Philadelphia in 1876. Doubtless many of our mature readers will remember viewing, as youths, with awe and wonderment, the great Corliss engine which stood at the centre of Machinery Hall, and furnished the driving power for all the exhibits in the building. There were seats for the public about the engines; the motion of the great flywheels created a breeze, and the engine was the admiration not only of the non-technical public, but of the members of the engineering profession from all over the world.

With the Corliss engine standing out prominently as a landmark in engine development, we appealed to President Alexander C. Humphreys, of Stevens Institute of Technology, for information as to progress in engine-building since that time. It will add a touch of human interest to the story to state that it then developed that Professor Robert M. Anderson, of the Department of Engineering, Stevens Institute, was in part influenced to his choice of a profession by seeing, as a boy, the big Corliss engine in Machinery Hall. By the courtesy of Stevens Institute we have the interesting sketch which follows:

To summarize in the briefest possible manner the progress which it records, the Corliss engine at the Centennial occupied about 54,000 cubic feet of space and consumed 2.2 pounds of coal to develop one horse-power; while a modern steam turbine of equal capacity will occupy 115 cubic feet of space and consume nine-tenths of a pound of coal to develop a horse-power, giving a saving in coal consumption of 59 per cent. According to Mr. Manning's estimate, that the average engine efficiency at the present time is 25 per cent. below the standard of the best type, the average now is well above the best of 1876; and, of course, the average efficiency in 1876 was much below the Corliss standard.

### Electric Power Transmission

Even more notable than the improvement in engine and boiler efficiency is the gain accomplished by the development of power transmission through the electric current. The transmission of power by electricity was unknown when the Centennial Exhibition was held, but in the year 1915 51 per cent. of all the power applied to industry in the United States, outside of transportation, was delivered by electric current, and as a result of all this development the total horse-power in use in the United States, to each million inhabitants, was 482,392 in 1915, as compared with 68,182 in 1879, or an increase of more than seven-fold. The facility with which power can be transmitted by electric current does away with the necessity of generating power where it is to be used. It can be generated at the most economical spot, as at the mouth of a coal mine or the site of a water-fall, and the industries which use it may be located in a spot more suitable to them.

### High Speed Reciprocating Engines

The introduction of the high speed reciprocating engine dates from shortly after Mr. Edison's invention of the incandescent lamp and development of the direct-current generator in 1881. The isolated lighting plants, followed by small lighting and power plants, gave an impetus to shaft-governed automatic cut-off engines, allowing of higher rotative speeds than were attainable with drop cut-off mechanisms. Among these were: the Buckeye, the Porter-Allen, the Fitchburg, the Armington and Sims, the McIntosh and Seymour, the Ball, the Westinghouse, the Willans, and many others. These were built simple and compound and were operated either non-densing or condensing. They varied in economy from 3.6 lbs. of coal per hour per B.H.P. for simple non-condensing to 2.15 lbs. of coal per hour per B.H.P. in compound condensing types.

Up to date the highest economy developed in reciprocating engines has been attained in the Stumpf (Straight) or Uniflow engine, obtaining a B.H.P. on 1.08 lbs. of coal per hour, same being in a 300 h.p. engine with an initial steam pressure of 130 lbs. per square inch absolute, and superheat of 261 deg. F. This record has been equalled by the best performances of stationary triple-expansion engines using steam at 170 lbs. per sq. in. absolute and 203 deg. F. superheat. The highest of all steam engine efficiencies so far reached has been obtained by the Wolf tandem-compound "locomobile," which consists of an internally fired through-tube boiler, having the engine combined so that the cylinders are jacketed by the final pass of the hot gases flowing to the stack—in other words, the cylinder projects into the smoke box. The initial steam pressure is from 175 to 225 lbs. per sq. in. absolute, is superheated to 800-850 deg. F. before entering the high pressure cylinder and again superheated to 450-500 deg. F. before entering the low pressure cylinder. The feed water is heated in an economizer in the breeching. The coal consumption of 1 lb. per hour per B.H.P. is common practice and 0.8 lb. per hour per B.H.P. has been attained.

### The Steam Turbine

The reaction type of steam turbine, known under his name, was first introduced in England by the Hon. Charles A. Parsons in 1884, and was introduced in the United States by the Westinghouse Co. in 1895, but it was not until about 1900 that it met with general approval. The DeLaval impulse turbine was introduced in its present form in 1889. The compound velocity impulse turbine, known as the Curtis, was introduced into the United States by Charles G. Curtis about 1896.

Since their introduction there have been many modifications and combinations of these types, better fitting their application to various power developments. For central station work the steam turbine has replaced the reciprocating engine. In fact, the turbine has the advantage in all electric generation, especially in the larger outputs. This is not, however, on account of better fuel economy, since for the same grades of machinery and equal ranges of temperature, pressure, etc., there has been found no appreciable difference in economy betwewen the best turbines and the best reciprocating engines, other characteristics influencing the preference. The real reason for the replacement of the engine by the turbine has been the greater compactness of the latter, thus resulting in a smaller investment in real estate.

### Boiler Efficiency

There has been marked improvement in boiler efficiency since 1876. The combined efficiency of furnace and boiler, being the ratio of delivered energy in the steam to that available in the fuel, ranges in coal-fired boilers from about 55 per cent. to 75 per cent. With liquid (oil) fuel and powdered coal, 80 per cent. is attainable. The most remarkable and promising development, the restriction being that the fuel must first be transformed into a gas, is the Bone system of so-called "surface combustion." This consists in burning a perfect mixture of gas and air in boiler tubes filled with porous refractory material, the result being incandescent combination, with no radiation or excess air losses. An effi-

ciency of 94 per cent. has been attained.

The development of the steam engine illustrates very clearly the part which capital plays in community progress. A steam engine is the servant of the community, no matter who owns it, and the improvements upon the engine, the changing over of power plants to bring them up-to-date, and the construction of new power plants, constantly absorb an enormous amount of new capital. Into such enterprises the profits of business largely go, while the resulting benefits go to the entire community. The man without property, who spends every dollar of his income the same week he receives it, is able to buy more with his wages, because steam engine efficiency has been doubled in the last forty years.

### Making Good War Losses

The world is suffering frightful losses through the war, and people are wondering what the effects of these gigantic debts will be upon the earnings of industry and the welfare of the peoples. We may learn something about this from the experience of the past. "It is our improved steam engine," wrote Francis Jeffrey in the "Edinburgh Review" in 1819, "that has fought the battles of Europe, and exalted and sustained, through the late tremendous contest, the political greatness of our land. It is the same great power which enables us now to pay the interest on our debt and to maintain the arduous struggle in which we are still engaged with the skill and enterprise of other countries less oppressed with taxation."

The steam engine which helped England bear the burdens of the wars with Napoleon was a poor affair compared with the engine of to-day, but even the latter, as Mr. Manning and Professor Anderson have indicated, may have its average efficiency in practice greatly increased. Beyond these prospective gains are those which lie in other sources of power, and in all the improvements in industrial equipment which are only partially introduced, or as yet only forming in the minds of inventors. More important than all these are the possibilities which lie in more thoroughly organized and harmonious industry, the development of intelligence and efficiency among the people, and the spread of a better understanding of common interests. We must look to these changes for gains in production which will enable society to overcome the losses of the war, and repeat the progress accomplished by the original application of the steam engine to industry.

## EARLY HISTORY OF THE WIRE-DRAWING INDUSTRY

By J. P. Bedson*

PUDDLED iron was at its zenith in 1872. The process of puddling devised by Henry Cort, who revived the art of making iron with raw coal, the secret having died with Dan Dudley, was on a sand bottom. It required two tons of pig iron to produce one ton of malleable iron, and though this amount was reduced later it was never possible to work with less than 30 cwt. of pig, and the labor was so great that only 2½ cwt. could be treated at a time. Attempts were made to reduce the waste, but it was not till 1820 that Joseph Hall, of Tipton, came upon the solution in the process known as "pig-boiling." That he made for his firm a reputation for quality second to none was largely due to the fettling used for lining the furnace, and much of his improvement in fettling depended on the employment of "bull dog," a calcined cinder from pig-boiling. But even in this improved process the work was most arduous and exacting.

Puddled iron was largely used in the wire trade for all common purposes, such as low-grade telegraph wire, armor for submarine cables, and fencing; but for the higher grades at that time English and Swedish charcoal irons were required, the former being made in the South Staffordshire district and in Shropshire. From 1850, when the first experiments in submarine telegraphy were made by the laying of a cable between Dover and Calais, the wire trade found an increasing demand for its productions, and Mr. Bedson mentioned that half of the wire required for the first Atlantic cable was drawn within 600 yards of the place where his audience were assembled. At the same works the wire was drawn for the first two wire bridges built in the United States by John A. Roebling, one being at Covington, Cincinnati, where the suspension cables were 1,760 feet long and were each composed of 5,200 wires, and the other the Niagara Railway Suspension Bridge.

### Continuous Rolling

A patent was granted in 1862 to George Bedson, of Manchester, for his continuous system of wire rod rolling mill, whereby rods could be rolled in 1 cwt. pieces, subsequently increased to 3 cwt., instead of small pieces of rod and coils of 14 lb. The three leading features of this mill were that the door of the heating furnace was placed immediately in front of the first pair of rolls, so that the heated billet when placed in them would draw the remaining length out of the furnace; that the rolls, 16 in number, were placed in line so that No. 1 delivered to No. 2, and so on, each roll being graduated in increased speeds to suit the acceleration of the reduced size of the billet as it progressed to the end of the mill, where the outcoming rods were coiled on suitable reels; and that a twisted guide was provided to present the partly-rolled rod to the succeeding pair of rolls, though this was required only once in the first mills when rolling iron. The rolls in the original mill were placed alternately horizontal and vertical, to give the requisite compression on top and sides alternately.

An experimental mill erected in the Adelphi, Salford, in 1857 proved successful, and was then removed to Bradford Ironworks, Manchester, where it ran till 1884. Of a second mill built in 1866 part is running to-day. A duplicate of it was built in 1867 for Messrs. Washburn and Moen, of Worcester, Mass., U.S.A., and from it, under the guidance of Mr. Charles H. Morgan, sprang the successful adoption of the continuous system of rolling not only in America but on the Continent and, in one instance, in South Wales. There is, however, a Sheffield installation of one of his mills which it is to be hoped will give an impetus to continuous rolling in this country. That system the author pronounced the greatest advance in rolling since it left the hands of Cort.

Another imperfection in the manufacture of wire besides the short pieces—the deteriorating effect of galvanizing on the wire—was remedied by Mr. Bedson in his continuous system of galvanizing, patented in 1860, which secured an excellent coat of zinc on the wire, perfect mechanical adhesions of the two metals, and maintenance of all the ductility and strength of the wire.

### Bessemer and Basic Steel

Next came the era of homogeneity, as against the fibrous iron given by puddled and charcoal material. In 1866 a ton of Bessemer steel was drawn, with good results. The material did not, however, displace the qualities of iron just mentioned, but gave the wire-drawer a stronger material in addition, thus increasing his ability to meet higher and extending requirements in engineering design. The treatment was much the same as for iron, except that the steel was heated only to a bright red for the rolling mill, whereas for iron a "wash heat" was required.

Basic steel, the invention of two Englishmen, Thomas and Gilchrist, created a great revolution in wire-drawing. Its great ductility made it ideal for the purpose, and through it the cost has been reduced and the work greatly simplified—so much so, that it would break the heart of a wide drawer to-day if he had to draw puddled iron to small sizes. The general use of basic metal began about 1884, and to-day it holds the premier position for wire-drawing purposes.

### Electrical Drive

In 1862 the author left Manchester to put down a wire rod rolling mill, a wire drawing mill, and galvanizing plant at Middlesbrough. He intended to use producer gas as the motive power, except for the rod mill, which was to be steam driven, but before his plans were completed his attention was drawn to what was being done with electrical drive on the Continent. The idea of driving each wire block direct from its own motor, suggested to him by M. Pieper, of the Compaignie de l'Electricité, at Liége, appealed to him strongly. Experiments were made with success, and a steam-driven dynamo of 600 h.p. was ordered, then the largest continuous current dynamo in the country. At the start over 40 individual motors, varying from 5 to 30 h.p. each, were required. This plant was the first in this country put down as a purely electrically driven plant.

## BUILDING A CANADIAN MERCHANT MARINE

A MOMENTOUS event in the industrial history of Canada was foreshadowed in the recent announcement by the Hon. C. C. Ballantyne of the national shipbuilding policy which is to be carried out by the Union Government. Some such action of this nature could hardly be otherwise than expected in view of parallel developments in allied fields both in Britain and the States.

It is now many weeks since the United States Government took over all the tonnage in course of construction in American yards for both home and foreign owners, and the pending action of the Canadian Government is but a natural sequel to the systematic transfer to British registry of ships which had originally been contracted for with foreign owners.

That such action on the part of the Government will meet with unanimous approval throughout the country is a foregone conclusion. One of the chief handicaps of the future and which till now seemed insuperable would have been the lack of tonnage wherewith to insure the world-wide distribution of Canadian products when commerce resumes its natural course. The lack of American-owned tonnage has been a consistent factor in retarding the export trade of that nation for many decades, and the certainty that the termination of hostilities will find the States in possession of a vast fleet of merchantmen is a source of much pleasurable anticipation to the manufacturing interests of that country besides acting as a desirable stimulant to the production of ships in the meantime. Much harmful lassitude may creep in unawares when it is felt that no permanent benefit of an individual nature would be derived from the shipbuilding activity of the Dominion, and visions of foreign-built and owned ships enjoying advantages in cost of production and choice of freights while Canadian yards were undergoing gradual disintegration are not calculated to insure the same degree of efficiency which would be otherwise obtained.

All of this uncertainty is removed, particularly by the fact that negotiations are already under way with the object of installing plate and shape mills at some suitable place or places best calculated to fit in with the present disposition of steel plants and the location of principal shipyards.

The certainty of an ample supply of material insured by these conditions may be offset to a considerable extent by financial consideration which no amount of well-intentioned government assistance can sidetrack. We refer particularly to the cost and availability of imported material which will be ruling when, if not before, such a plant as essayed by the Government could be obtained and put into operation.

Equipment such as is required can only be obtained from the States, and under present conditions contracts for such machinery would have to receive approval and some degree of priority in delivery by the United States authorities if it is to be had inside of two years. A plate mill capable of producing maximum size plates as used in the construction of 10,000-ton boats would have an annual capacity largely in excess of our requirements, and the cost of maintaining the plant idle for perhaps six months in the year would have to be taken care of by Government subsidy. Certainly the cost of producing ships in this manner could not be expected to equal that in other countries where continuous operation was possible.

The deciding factor would therefore be as to whether the shipowners or the nation in general should pay the extra cost involved through using Canadian plates. If conditions could be foreseen accurately enough to determine the certainty and amount of foreign material which could be obtained at any specified time, the advisability of installing plate mills might be seriously questioned. The possibility of securing equipment may be increased through diplomatic channels to a degree which would be most desirable in insuring, through the availability of material at a suitable cost, the continuance of shipbuilding in this country during the most critical time,—the transition period, when competition with the world would begin to assume an important influence on affairs. The most important benefit, however, is the insurance of a supply of bottoms wherewith to transport Canadian products, and the maintaining of the freight rates at reasonable levels, as indicated by the announcement referred to.

## WHY NOT A PRIORITY BOARD?

ALTHOUGH somewhat belated, the announcement that the Dominion Government contemplate assisting in an effort to increase the production of iron and steel will be received with gratification in manufacturing circles. For some time the shortage of iron and steel has been becoming acute and has more recently assumed serious proportions, particularly since the enormous demand in the United States necessitated the introduction of an embargo. It is of vital importance that a sufficient supply of steel should be available for those of our industries engaged upon the production of munitions and other war supplies. Shipbuilding and the railways, of course, come under this category.

Although few details have been given out, the time seems opportune for the creation of a Priority Board to distribute available supplies of steel, etc., where most urgently required and to generally supervise the production and consumption of iron and steel, so that every pound may be used to the best advantage. The effect of such a system would be both immediate and beneficial. The Priority Board at Washington has been a great success and is a good precedent to follow. A board at Ottawa could not regulate prices to the same extent but could do more valuable service in the distribution of materials. Prices at this time are of secondary consideration; the urgent need of steel is the primary factor in the situation.

The appointment of a Priority Board does not necessarily mean any drastic interference with the management of the different steel companies but could be used as a species of clearing house and arrange production schedules with the mills. Such an organization would be able to speed up the delivery of raw materials to the mills and ensure maximum operating capacity at all times.

# INDUSTRIAL NOTABILITIES

JOHN JOSEPH HARTY, president and director, Canadian Locomotive Co., Kingston, Ont.; director, Dominion Steel Foundry Co., Hamilton, Ont.; director, Hamilton Steel Wheel Co., Hamilton, Ont.; director, Wabasso Cotton Co., Three Rivers, Que., was born in Kingston, Sept. 16, 1874, son of the Hon. William and Katherine Harty (deceased).

He received his education in Private School, Kingston; Kingston Collegiate Institute; and St. Mary's College, Montreal; graduating later from Queen's University, Kingston, with degree of M.D., but never practised medicine.

JOHN JOSEPH HARTY

In 1899 Mr. Harty engaged in real estate business with Strong & Ireland, New York, and joined the Canadian Locomotive Co., Kingston, in 1900, as secretary. He became vice-president and general manager in 1916, and has been president since Sept., 1917.

Mr. Harty's civic activities include six years' service as alderman of Kingston, representing Cataraqui Ward.

His clubs are: Frontenac; Kingston Yacht; Thousand Islands Yacht; Thousand Islands Country; Kingston Golf and Country; R.C.Y.C. and University (Toronto); University (Montreal). Golf, motor-boating and motoring are his principal recreations.

Mr. Harty married Anna Fitzhugh Powell, April, 1906, and resides at Kingston, Ont.

# Ottawa to Take Steps to Relieve Iron and Steel Situation

*Authorities Recognize Necessity for Increased Production in Addition to Equitable Distribution—Trade More Settled Since Fixing of Price Schedule—Coal Shortage Causes Mill Activity—Non-Ferrous Metals Unchanged.*

RECENT announcements at Ottawa indicate that official notice has been taken of the acute situation in the iron and steel trade. Conditions in respect to the shortage of iron and steel are getting worse and in view of the necessity of utilizing all available supplies to the best advantage, efforts will be made not only to increase production but to supply those industries which are most in need of raw materials. Munitions, shipbuilding and railways require steel and it is of vital importance that there should be sufficient steel available for these purposes. It is also important that the non-war industries should not be entirely cut off from supplies of iron and steel. There is a more settled feeling in the trade now that the fixed price schedule has been extended for three months. Prices of steel products remain firm and unchanged. The severe weather has played havoc with operating schedules and the freight congestion is worse as a result. Both coal and coke are in short supply which is curtailing operations at the mills and adversely affecting the industrial situation generally. Prices of non-ferrous metals are unchanged this week and there is practically no change in the general situation. Tin, in future, will be shipped across the Pacific and permits will not be necessary. Prices of a number of lines of machine shop supplies have advanced, while the machine tool business generally is somewhat quieter than usual.

MONTREAL, QUE., Jan. 7, 1918.—The general industrial situation is again moving in its regular channels after the quiet period of the holiday season. Markets have been more or less disorganized by the pronounced delay in getting delivery of raw-materials. The Canadian situation at present is less acute, the milder weather enabling the railroads to maintain a higher efficiency in operation. Present activity is normal but prospects are for an increase in the near future.

### Steel

Conditions are beginning to show some sign of improvement and the acute situation that has been so pronounced for several weeks past is taking on a more encouraging tone. The relief that was anticipated by the recent developments in the railroad situation, both here and in the States, has not yet been particularly emphasized, but operations are begining to indicate that the near future will mark a turn for the better. While every effort has been made to conserve the available supply of coal, the shortage has been so pronounced in certain districts that the closing down of industries and the curtailment of heating in many public buildings has been a feature of the past few weeks. Immediate relief can only be realized by the most efficient co-operation of the manufacturers and the railroads to facilitate the movement of coal from the source to the destination. The production of iron and steel has suffered greatly from the inability to secure sufficient fuel for maximum operation, and many temporary close-downs have been necessary.

The Canadian situation has been more or less affected by the American developments owing to the inability of obtaining delivery of much needed materials. The situation is the all-absorbing problem at the present time as it is practically impossible to secure the required quantity from the United States. Steps are, however, being taken by the Canadian Government and other interested parties to establish new or additional units to existing steel plants with a view of increasing the output of steel plates of a grad erequired for shipbuilding purposes. While nothing definite has yet been announced in this connection, it is anticipated that in the very near future action will be taken in this very important matter. With the understanding that existing prices in the States will continue for several months without further adjustment or revision, the dealers here do not look for any immediate change in quotations now ruling. Local business has been quiet owing to the difficulty of getting delivery of material.

### Metals

The possibility that some revision would be made by the American Government in connection with the prices now ruling in the copper and other commodities has practically been dissipated by the announcement that it is very unlikely that any further readjustment would be made for at least three months and probably longer, as the present system of regulation is in most respects entirely satisfactory. Copper will remain at the price fixed as demands are well within the output of the refineries. Tin is still a feature, as relief on this side has not yet followed the sharp decline on the London market. Spelter is not active but continues firm. Lead is again returning to a stronger position. Antimony and aluminum are both firm and unchanged.

### Copper

With the definite announcement that no early change will be made in the price that governs the sale of copper in the States, the situation has taken on a settled aspect with producers and consumers well satisfied. Owing to the great falling off in the demand for domestic purposes the present production is ample for war requirements. The demand locally has been a little more active following the holidays, the steady tone of the market being well maintained with prices firm at 32 and 33 cents per lb.

**Tin.**—The acute condition that has characterized the tin situation for several weeks shows signs of relief, but the tension is still felt on this side of the Atlantic. The London market recorded a drop of £22 per ton over that quoted last week but so far this easier tone has not affected the price of tin on the New York market, the uncertainty of shipments still being a factor. Supplies on the local market are not abundant but sufficient to meet the requirements of the trade. Quotations have declined one cent during the week, dealers here asking 76 cents per lb.

**Spelter.**—The market has developed a slightly firmer tone following the placing of American Government orders for fairly large supplies. Stocks on hand are, however, more than sufficient to meet all demands and no immediate strength is looked for. Domestic inquiry is light but with a better undertone. The market here is steady and quotations are firm at 10½ cents per lb.

**Lead.**—A renewal of interest has developed in the lead situation owing to the strength shown during the past week. In addition to the increased demand, the apparent reluctance on the part of sellers to accept orders has awakened the waning interest of consumers, the latter showing some anxiety to cover their requirements. The return to the stronger position is shown in the advance on the New York market, the quotation of 6½ cents for Trust and 7 cents for independents representing an advance of ¼ cent per lb. Local dealers report a stronger market and quotations have advanced ¼ cent during the week, the current price being 9¾ cents per lb.

**Antimony.**—The market is devoid of feature and the demand light. The firmness of the New York situation is maintained as a result of recent reports that the American Government would soon be buyers of considerable quantities of metal. The local market is quiet with price firm at 18 cents per lb.

**Aluminum.**—This market continues steady and firm with quotations well maintained; local dealers are asking 60 cents per lb.

### Machine Tools and Supplies

The opening week of the New Year has not developed any marked activity in the machine tool industry but the prospects are encouraging for a continuance of a fair volume of business throughout the winter months. The recent placing of American shell orders has somewhat revived the interest of machine tool builders and considerable equipment has been placed for this type of shell. It is anticipated that more orders may be placed and also further British shells which will call for additional machinery. In some respects, however, the plants that will receive this business are already well equipped with the necessary machinery, and the new tools that may be required will be more a question of replacing those that have become unsatisfactory for production purposes. The demands for general equipment are showing signs of declining but the volume of business in this respect is still of an encouraging character. Inquiries for machine tool supplies and general shop necessities have shown a slight increase and the continued activity in the manufacturing industries appears to indicate that present activity is on a par with that of the past several months. All quotations are firm and well maintained.

### Scrap

Activity in the old metal market has been affected by the difficulties experienced in transportation. Dealers are still at a loss to understand the attitude of the American Government in connection with the scrap situation and the market as a result, has been comparatively quiet, business being of the restricted character. It is expected that when the wishes of the Government are thoroughly understood and the dealers are satisfied with this ruling that conditions will again return to their normal state. Local conditions are more or less reflected in those prevailing in the States and dealers here report a very quiet market and light business; quotations are unchanged and firm.

## Toronto

TORONTO, Ont., Jan. 8.—The Dominion Government purpose to take a hand in relieving the acute situation in the iron and steel trade will doubtless be productive of good results. According to reports from Ottawa, an ambitious scheme is under contemplation whereby the production of steel in Canada is to be considerably increased. The Government also propose taking over the shipbuilding plants and undertaking the construction of a large number of steel vessels, involving a large sum of money. It is to be honed that there will be an improvement in the coal situation. Fuel Controller C. A. Magrath has been to Washington and, as a result, coal shipments are to be given precedence at the border over everything else. Special arrangements have been made with the railways to this end.

### Steel

The recent announcement at Ottawa relative to the conditions in the iron and steel trade indicates that a determined effort will be made to relieve the present acute situation in so far as this is possible. The supply of steel is proving inadequate to meet the increasing demand. The shortage which has existed for some months is getting worse and has reached a point where something must be done to avert a most serious state of affairs. The Imperial Munitions Board, representatives of the railway companies, and also of the steel companies met in conference at Ottawa last Thursday and Friday to discuss ways and means of relieving the shortage of iron and steel supplies for munitions, railways and industrial purposes. Plans were discussed for co-ordinating supplies as far as possible, according to relative necessities.

It is understood that the Dominion Government has under consideration plans for increasing the iron and steel output in Canada, and it is possible that some arrangement will be made for helping to finance extensions of present plants or else for the establishment of new plants, especially in regard to the production of steel plates for shipbuilding. Another matter discussed was the supply of steel for rails, of which the railways are in great need. It is believed that the Government will take action at once to increase the output of steel rails to meet the essential requirements of the railway companies.

**CANADIAN GOVERNMENT PURCHASING COMMISSION**

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

It will be interesting to see what steps the Government propose taking to increase the output of the steel products mentioned in view of the difficulty that will be experienced in obtaining machinery for rolling plates and rails. There is no question as to the need of these materials, but their manufacture presents difficulties not easy to overcome under prevailing conditions. What will likely be done first is to form a Priority Board similar to the one at Washington. By this means the rolling schedule and other operations at the mills can be regulated in accordance with the requirements of the consumers and the output distributed where it is most needed.

Locally the steel market is quiet and there have been no price changes this week. The extension of the price schedule by the War Industries Board, Washington, has been well received in the trade, and the market is more settled on this account. The maximum prices will be continued in effect until March 31. It was further directed that no contracts calling for delivery of any of the commodities included in the schedule on or after April 1st are to specify a price unless the contract includes a clause making the price subject to revision by Government agency. Prices of steel products are holding firm, and in view of the heavy demand for steel products there seems to be little possibility of a decline in prices at any rate for the first quarter. The continued severe weather is seriously interfering with the movement of freight on the railways, while the output of the mills has been further restricted due to operating difficulties and shortage of fuel.

### Pig Iron

The severe weather has seriously interfered with the movement of coke and the shortage of this material is getting more acute. The Steel Company of Canada has been forced to bank one of its blast furnaces at Hamilton owing to the difficulty of obtaining coke, and has consequently withdrawn prices on foundry iron. This furnace was producing foundry iron, the other furnace producing basic iron. No general revision of coke prices is expected to be made throughout this year, according to the latest statement by Dr. Garfield, United States Fuel Director. Prospects have not improved for Connellsville coke shipments aside from promise of better things under Government railroad control. As yet Government control of the railroads in the States has not made a perceptible effect upon either coke or iron, but it is hoped that with an improvement in traffic conditions the coke situation will be considerably bettered, which in time will materially help the production of pig iron. H. Bayne, Dominion Controller of Metals, has gone to Washington to discuss with the officials there the pig iron supply in the States available for Canadian manufacturers.

### Scrap

The scrap metal market continues dull, with no improvement to note. Prices of steel and cast iron scrap are holding firm, but copper, lead and spelter continue weak. The maximum price of No. 1 heavy melting steel has been fixed at $30 per gross ton at any consuming mill in the United States.

### Machine Tools

The machine tool market is still rather quiet. Some munitions plants are being equipped for turning out 6-inch shells. The freight congestion, due to the severe weather is holding up shipments from the States; delay is also being caused by the necessity of obtaining licenses before tools can be shipped.

### Supplies

Business is fairly active and prices are still advancing on a number of lines. Pratt & Cady pop valves have advanced,

while water proof valves of the same make are also higher in price. As a result the [illegible] pipe cutters, [illegible] now quoted at 40 per cent. off as against 45 per cent. off list. Pipe extractors are also higher, being now quoted at 12½ per cent., as against 25 per cent. formerly. Higher prices on Manila rope are expected on account of the upward tendency in fibre.

### Metals

Business in the metal trade has been rather quiet this week, not having recovered from the effect of the holidays and stock-taking. There have been no important developments and conditions in the markets remain much the same as for the past few weeks. No activity in the copper market is looked for now that the producers' committee control the distribution of supplies, and the price is fixed; speculation is, of course, impossible. Tin is at a standstill, there being no spot metal and no transactions. Lead is firmer, but unchanged, while spelter is also the same price as last week. There has been no change in either antimony or aluminum.

**Copper.**—No marked change in the copper trade developed during the past week. The producers' committee continues to judiciously release metal to dealers in carload lots, with full regard to the prior necessities of the Government and Allies. Routine conditions prevail in the market and no material change in the situation is expected on account of the price being fixed and distribution under control. Prices locally are unchanged, lake and electrolytic being quoted at 32c and castings at 31c per pound.

**Tin.**—This metal has been placed on the war material list, which will eliminate all speculative trading. No more permits are to be issued for the shipment of tin from London to this side. All consignments for the United States and Canada will have to come via Singapore, and will not be subject to permit restrictions. This means that shipments of tin will in future come from Singapore via the Pacific. Prices are unchanged and nominal at 80c per pound.

**Spelter.**—The market is quiet, but producers are holding to their quotations and the price is firm at 10½c per pound.

**Lead.**—The leading interest has advanced its price in New York to 6½c, or ¼c over the previous quotation. This has strengthened the market and created a better sentiment in the trade. There has been as yet no change in price locally, and lead is still quoted at 8½c per pound.

**Antimony.**—The market continues dull and weak. The demand for antimony is high and quotations nominal and unchanged at 18c per pound.

**Aluminum.**—The market is steady and quiet, with quotations unchanged at 62c per pound.

## Sydney

SYDNEY, N.S., January 3.—Closely appCroximate figures at the end of 1917 [illegible] of Nova Scotia [illegible] than anticipated, owing to the great falling off in the last few weeks of the year. The total production was 5,687,000 tons comparing with 6,171,424 tons in 1916, a drop of well over half a million tons. Production during December was at a very low ebb. The Glace Bay collieries of the Dominion Coal Company put out only 236,000 tons, this being the smallest monthly output for ten years—with the exception of the strike period. Away back in 1902 these collieries were getting larger outputs at comparable seasons. The Inverness Coal Co. shows a rapid decline in production, and the output of the Acadia Coal Co. was adversely affected by the necessity of closing the Albion Slope because of fear of an underground fire. A snowfall on New Year's Eve—said to have been the greatest in 40 years—has thoroughly disorganized production in Cape Breton, and coming on top of the broken period of the Christmas holidays, has caused a quite unprecedented coal shortage locally. The Dominion Steel Company's plant has been completely or partially closed down for several days, and will not resume full operations for a number of days. Coal production seems to be going from bad to worse.

### Wage Dispute

The appointment of a tribunal is expected to adjust the wage question between the Amalgamated Mine Workers and the coal companies of the Sydney District. The Dominion Coal Company has increased the wages of its workmen in the period from June1, 1916, to May 1, 1917, by an average of 40 per cent., and has now offered a cumulative advance, on top of the 40 per cent. mentioned, of ten cents per day to men rated below $3.00 per day, plus a general increase of 12½ per cent. This means that within a period of 18 months the Dominion Coal Company has offered increases to its workmen aggregating 57 per cent. This last-named offer the Amalgamated Mine Workers refuse even to consider, and events are now awaiting the decision of the Minister of Labor as to the appointment of a tribunal to settle the disagreement.

The Dominion Coal Company has announced that its offer in any case is retroactive to the 1st of January, 1918. It has been stated the miners would, in case of refusal of their full demands, limit their work to four days per week, but it is not thought the general body of the men would follow their leaders to this extent, and in face of the unusual coal shortage neither the public or the government is likely to tolerate any stoppage of work.

## New York

NEW YORK, Jan. 5.—Because of the war the United States machinery industry transacted as much business in 1917 as in any three previous years in its history. It would not be surprising to find that contracts placed in the last twelve months for machinery and machine tools, to equip arsenals, navy yards, ordnance plants, shipbuilding works, airplane engine plants, and other mills and foundries engaged in the manufacture of war munitions, have called for the expenditure of $1,000,000,000. The buying movement is far from being over, although a lull was evident during the holiday period. In fact, the additional heavy appropriations called for by the United States Shipping Board to acquire and to build more shipbuilding plants will make further heavy drafts upon the resources of the machinery makers.

Productive capacity of the machinery factories in 1917 was increased from 50 to 150 per cent., but facilities are still inadequate to meet the pressing needs of the Government and manufacturers of war munitions. The Rock Island arsenal has distributed additional orders among tool builders calling for the expenditure of $1,000,000. Deliveries of these machines are to be made at various times over the next six months. Other Government orders will be closed in the next few days.

### New Ship Appropriation

Through the Secretary of the Treasury the United States Shipping Board has asked the House for an additional appropriation of $82,000,000 to acquire and establish shipbuilding plants. For the construction of new ships other than those for which contracts have been placed an additional appropriation of $701,000,000 is asked which will bring the total to be expended for construction of ships alone to $1,935,000,000. The Sound Shipbuilding Co., which has taken over the plant of the American Arms & U-boat Corporation, expects to obtain a contract for ships from the Emergency Fleet Corporation, and is now negotiating for cranes and machine tools. The Todd Shipbuilding Corporation has acquired the Puillon shipyard in Brooklyn, which it will utilize for boat repairs.

Additional heavy tonnages of steel plates and shapes for shipbuilding have been distributed among the steel mills by the War Industries Board. Canadian shipbuilders have also been seeking ship steel from American mills and have secured a moderate tonnage from plants on the lakes. Specifications are being prepared for large tonnages of steel sheets, which the Government will require to be shipped to manufacturers of war munitions.

### Railroad Equipment Contracts

Now that the Government has taken over control of the railroads, the plans to provide transportation companies with adequate equipment will be pushed. It is understood that specifications are in preparation for the building of 100,000 cars and several thousand locomotives for domestic service, and the steel mills will necessarily be called upon to furnish upward of 2,000,000 tons of steel to build this equipment. The War Industries Board has distributed orders for 9,000 freight cars for Italy, most of which will be constructed by the Standard Steel Car Co. and the American Car & Foundry Co., as these builders have steel which was designed for executing

the Russian contract, now suspended, which can be utilized in large measure to build cars for Italian service.

A large contract for machine guns has been placed by the U. S. Government with the New England Westinghouse Co. Heretofore the Westinghouse company has been manufacturing Russian rifles under contract with the British Government. Satisfactory arrangements have been made between the U. S. and British Governments by which the Westinghouse plant becomes available for manufacturing the heavy type of Browning gun for the U. S. army. Some purchases of machinery will be necessary to enable this plant to make machine guns instead of rifles.

## Pittsburgh

PITTSBURGH, Pa., Jan. 7.—This week opens with operating conditions at blast furnaces and steel works slightly improved. Although there is a somewhat freer movement of coal and coke, the supplies are still deficient at practically all the furnaces, and the percentage of banked furnaces resuming operations has thus far been very small. Consequently the production of iron is still on a greatly reduced scale.

### Traffic Conditions

The railroads remain very much congested, but are making strenuous efforts to improve matters. Iron and steel interests are all hopeful that the operation of the railroads by the Government will result in material improvement in traffic conditions, but they do not look for much change in the situation for a few weeks. Despite the fact that several additional embargoes have been placed, it is the belief that several months will elapse before the full results of the taking over of the transportation facilities will be felt.

### Pig Iron

The market for pig iron and finished steel products remains absolutely stagnan. Commercial demand is insignificant all along the line, and will likely remain so during the first quarter. Most of the consumers have bought for their full requirements covering a period of three months in anticipation of a revision in prices after March 31. On the other hand, the selling interests claim there is a big unsatisfied demand, and they look for a larger volume of new inquiry for small individual lots.

Following the formal announcement at Washington, as presaged in the last report, that there will be no iron and steel price revision before March 31, contracts are being made for Lake Superior iron ore for the season of 1918 at the prices ruling for the 1917 season, but with a proviso that they are subject to readjustment in case prices are changed later.

Big-head keeps more men from succeeding in this world than lack of education was ever accused of doing.

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE—Valparaiso, British Consul General.

COLOMBIA—[illegible] eeral.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE—[illegible] Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Bahia, British Consul. Rio de Janeira, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

### CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. L. Crowe, Acting Canadian Trade Commissioner, P. O. Box 102, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Gerretd, Acting Canadian Trade Commissioner, Zandbaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Pensch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

### CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—[illegible], Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

### CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

## CANADA'S TRADE POSITION

COMMENTING on the thrift of Canadians the "Wall Street Journal" says:

Canadian foreign trade for ten months of 1917 approaches $2,000,000,000—a per capita of $2,000. Of but recent development, the volume of commerce for the whole year will doubtless nearly equal in dollar value our own foreign trade for 1900, when we had 97,000,000 people. With but one-thirteenth our man-power, Canadian exports and imports will exceed one-fifth of our own.

It may be said low cost production and high prices of farm exports and manufactured food and shipments of military supplies have made this possible. But in reckoning these factors the adverse [illegible] in which Canada had the opportunity to lay the foundation for future international trade must be given due consideration.

### Position in 1914

In the summer of 1914 Canada was tentatively surveying the means of recovery from continent-wide liquidation. In the west and also in the east a prolonged real estate boom had collapsed, coincident and correlative with a severe contraction of commercial credit and radical readjustment of domestic trade in volume and method. It was a moot question whether real business revival would manifest itself in the autumn of 1914 or the following spring.

Credit was in its most sensitive stage of convalescence, when the declaration of war came as a clap of thunder from a cloudless sky, and 100,000 industrial effectives went voluntarily to the colors. The supply of labor was never adequate to pioneer construction; nevertheless, over 400,000 men went into service voluntarily from all classes and from the most productive occupations.

### War Bonds

At least $500,000,000 of war bonds have been purchased by the Canadians. The Ministers of the Crown were justified in the implicit confidence which they placed in the Canadian instinct of thrift. There are racial and political differences in Canada, but thrift in common, homely household terms, is a Dominion-wide virtue, characteristic of the passive and the unaggressive, as well as of the industrious and ambitious.

## CANADA'S PRODUCTION

The value of production in Canada during the year ending to-day from field crops, forests, mines and fisheries, according to the *Monetary Times*, was approximately $1,507,667,000, compared with $1,275,734,812 in 1916. The value of production (field crops, mines, fisheries and forest products) in 1908 was $703,590,000.

For the first time on record, in 1917 the value of Canada's field crops was over $1,000,000,000. This was due to the high prices prevailing.

## SOME ASPECTS OF SHIP DESIGN

THE present activity in shipbuilding, combined with the fact that most of the tonnage is for ocean use has directed considerable attention to the various bodies under whose supervision the vessels are constructed. Attention was drawn recently to an agreement between the leading registration societies whereby greater uniformity of specifications would be obtained. The difficulties of operating under the previously existing variety of requirements was exemplified by a writer in the Times Engineering Supplement who dealt with the possibilities of saving steel in ships.

### Draught and Strength

In designing warships or special types of merchant vessels calculations are made to decide whether the vessels will be strong enough for their intended work. These calculations are very complicated and involve a large amount of labor. The ship is treated as if she were a beam supported by her buoyancy, which is equal to her displacement, and loaded with weights made up of her own weight and that of any loads she may be carrying. This gives the bending moment and shearing force at any point in her length.

The value of these factors will vary in accordance with the distribution of the buoyancy and weight, but the maximum bending moment will occur at or near amidships, and the shearing force will have a maximum at about the quarter lengths of the ship. The strength of the section can be estimated at any point so that the stresses acting can at once be determined. Usually if the strength is sufficient amidships it will be so throughout. In special cases, however, the strength is estimated at any doubtful point and the material disposed accordingly. It should, of course, be understood that these calculations are not to be regarded as absolute. They really form a means of comparison between vessels, and it is doubtful if the stresses obtained by this means really represent those actually existing in a vessel at sea.

In ordinary merchant vessels calculations are not required. Registration societies have drawn up tables of scantlings for steel vessels by means of which the necessary strength in any ship can be provided. These tables have been derived to some extent by calculation, but for the most part they are based on experience. It is not surprising, therefore, that similar vessels built under different societies' rules vary in strength.

### Work of the Load Line Committee

The greater the displacement of a ship the larger will be the forces acting on her. The question of the relation between draught and strength of ships was very fully dealt with by the Load Line Committee. This committee estimated the strength of various ships at their amidships sections with steel scantlings as fixed by the four principal registration societies. The values were found to vary, and they were plotted as curves having for their base the length to depth ratio of the ship. Fair curves were drawn for each society, representing the minimum values, and a minimum curve was then drawn which was taken as a standard by the Load Line Committee. It was found that the strength of the section varied directly as the draught of the ship, the beam, and as a factor depending on the length of the ship. A standard of transverse strength was also investigated by the committee and determined in a similar way to the longitudinal strength. It follows, therefore, that in most cases the scantlings at present adopted by the registration societies will give a strength greater than the standard. Hence it is to be expected that some modifications will be brought about in the rules of the societies with the object of reducing the amount of steel in merchant ships.

The rules, however, have a further application which is important. The standard of strength set up by the Load Line Committee refers to vessels running at a draught equal to the maximum laid down by the Load Line rules. Many ships are built the carrying capacity of which is determined by the cargo space available rather than by the cargo weight. Such vessels cannot stow a sufficient weight of cargo to load them down to the maximum permissible draught. In consequence, the forces brought to bear on them are less, and their strength could accordingly be reduced in the direct ratio of their actual draught to the maximum. The registration societies have partly recognized this consideration already. Lloyd's Register will allow a reduction in scantlings for vessels carrying a limited amount of cargo with a fixed freeboard. Germanischer Lloyd specifically state the reduction in scantlings for reduced draught, but fix a maximum reduction which can be applied to the longitudinal and transverse structural parts. These reductions apply to the half length of the vessel amidships. At the ends only half the amount is allowed. The principle used is that the strength of the ship must vary as the draught. Bureau Veritas adopt a similar procedure to the German society, and state that all the midship tabular scantlings, that is the scantlings of the strength parts, may be reduced in the direct ratio of the proposed draught of water to the full draught allowable, while the scantlings at the ends are to be those which correspond with the reduced midship scantlings. A limit below which the scantlings are not to be reduced is fixed.

### Subdivision

In addition to the reason already given for many ships running at draughts below the maximum permissible there is now the operation of the International Convention Rules to be taken into account. Any vessel carrying 12 or more passengers comes under this convention, which fixes the subdivision in accordance with the freeboard ratio—that is, the ratio between the freeboard and the draught. While it is theoretically possible to put a sufficient number of bulkheads into a ship to enable her to run at her maximum draught and still fulfil the convention rules, the result will often be the introduction of so many bulkheads into the ship that she would not be satisfactory commercially. In consequence,

---

in order not to diminish unduly the length of holds, fewer bulkheads will be fitted and the draught reduced below the maximum. It will be some compensation for this reduction in draught if the registration societies allow the scantlings to be reduced.

In fixing the scantlings for a ship from the rules of a registration society reference is made only to the principal dimensions, and these take no account of the deck erections. On the other hand by the Load Line rules the greater the erections the greater can the maximum draught be. In considering Lloyd's rules, for instance, the midship scantlings for a ship with erections will be the same whatever the extent of these, provided the centre or bridge erection is not less than the minimum length given by Lloyd's Register for long bridges. Taking a particular ship, say, 510 ft. long, the load draught would be about 31 ft. 4 in. if the bridge was of the minimum length of 102 ft. If the length of the bridge were increased to 306 ft. and a poop and forecastle added, each 64 ft. in length, the load draught would be 33 ft. 1 in. Therefore, although the two ships would have the same strength amidships, the calculated forces brought to bear on the latter would be 5½ per cent. greater than on the first. If the three erections were now merged into one, that is, the ship made into an awning decker, the permissible load draught would be 34 ft. 1 in. Here again the midship scantlings would be unaltered, but the forces acting on the ship would be about 9 per cent. greater than in the first case. If the process of increasing the erections is still continued and a centre erection added on the awning deck the load draught must still remain the same, although in this case the strength would have been increased.

### Types and Freeboard

To fix the scantlings of a ship so that she may be suitable for her work and still fulfil the rules of the registration societies attention should be given to the relation between her draught and depth. An awning-deck vessel must run at a less draught than a similar vessel having an upper deck in the same position as the awning deck. In the first case the load draught is fixed from considerations of strength, but in the second from considerations of reserve buoyancy. The latter vessel, however, can have a greater draught than the former because she is a stronger ship. If the strength of the awning-deck ship is increased her draught can be increased in proportion. At least, this was the rule, but nowadays it is no uncommon thing to find awning-deck ships running at the same draught as full scantling or upper-deck ships. Shelter-deck vessels are of the same strength as awning-deck vessels, and it will be remembered that some time ago the Shipping Controller gave permission for these vessels to run at a load draught equal to that of a full scantling ship, provided certain rules were complied with. The carrying out of these rules, however, did not increase the strength of the vessels.

Perhaps the best illustration of how steel can be saved by careful attention to the relation between the draught and depth is given by the case of an awning-deck vessel having a complete deck added over her, the draught at which the vessel is required to run being that given by assessing the freeboard from the awning-deck. In the ordinary way the deck over the awning-deck—that is, the shade deck—would be taken as an awning deck. This would considerably increase the scantlings, as compared with the assumption that the second deck down is an awning-deck. The scantlings for the shade deck would then be the same as for an awning-deck. The awning-deck itself would be treated as a first deck, and so on. A further reduction in the scantlings would be brought about by the fact that the length to depth ratio can be taken to the shade deck, so that altogether an appreciable weight of steel would be saved.

It is quite clear from what has been said that there are many merchant vessels running at the present time of greater strength than they need be if existing knowledge on the subject were properly applied, and it may be anticipated that after the war a revision of the rules will be brought about which will effect considerable savings of steel.

# ANNOUNCEMENT

Our Service Department, realizing the necessity for securing equipment for the manufacture of shells owing to the difficulties attendant on the importation of Machine Tools from the United States, have purchased the Drawings, Patterns and jigs of the famous

## "Montreal Shell Lathe"

**FOR BORING AND TURNING 6" AND SMALLER SHELLS**

This Lathe was designed and developed by the Montreal Foundry & Machine Co., and has attained an unexcelled reputation among Munition Manufacturers on 6" Shell Operations.

We have completed arrangements for the manufacture of this Tool with a well known Canadian Machine Tool Manufacturer and expect to be making deliveries in the near future.

Our SERVICE DEPARTMENT will be pleased to send you specifications, prices and deliveries.

## A. R. Williams Machinery Co., Ltd.

**64-66 FRONT STREET W., TORONTO**

# Are you the man we need?

SOMEWHERE in Canada there's a man we would like to meet.

He may be a machinist, an office man, timekeeper or salesman. He may not be able to boast a college education, but so long as he has ambition and good judgment a lack of the higher education will not prove a handicap.

The man we want is a man whose fighting spirit would have carried him to France had he not been prevented. A man with energy and push and ambition and resourcefulness.

The work we have in mind for such a man might not be congenial at first (to a man lacking the qualities named) but it would prove the open door to splendid opportunities later (and not so very much later either, perhaps).

If you are not satisfied with your present outlook and feel, right down in your heart, that you could SELL (with proper direction), then write us.

If you are a hustler, prove it by replying promptly to this advertisement, and to prove you are thorough-going, give full particulars as to age, experience, present salary, etc. Replies will be considered strictly confidential.

Box 364,
CANADIAN MACHINERY.

# Steel FLUMES and PENSTOCKS

## For Water Powers

Send us your specifications and allow us to submit a price.

## Smoke Stacks

**Large or Small.**

We are prepared to build steel smoke stacks any size required. None too large or too small for our capacity. Prices reasonable.

## Steel Tanks

**Any Size or Shape.**

Hundreds of our steel tanks in use, and for nearly as many purposes. Made tight, and made right. No design too complicated or too simple for our experts. Let us figure on your requirements.

## Steel Piping

**Straight or Curved.**

Our shops have turned out some very difficult jobs of steel piping, and the many repeat orders furnish the best evidence of satisfaction to the buyers. Let us see your drawings and give you a price.

# INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## ENGINEERING

**Cobalt, Ont.**—Contract has been let for the construction of a [illegible] at a [illegible] property near Amos, Que.

**Ingersoll, Ont.**—An explosion of mysterious origin in the plant of the Ingersoll Gas Co., on Jan. 2, has almost entirely destroyed the plant.

**Toronto, Ont.**—The City Architect has issued a permit to W. G. Bell to build a one-storey frame and iron workshop at the corner of Dufferin and Geary Avenues at a cost of $1,200.

**Dundas, Ont.**—The John Bertram & Sons Co. will build a new shop on the site of the old pattern shop. The building will be of brick and steel construction, 70 ft. by 300 ft., and will cost about $150,000. The contract has been let to Secord Co., of Brantford.

**Quebec, Que.**—Official announcement was received here from Ottawa recently that the Ross Rifle Factory will reopen shortly. For military reasons little is being said about the matter at Militia Headquarters, but it is understood that the factory will be engaged in making parts, in reconverting and, particularly, on certain work which has been secured from the United States Government for rifles to be used for training or other purposes.

**Chatham, Ont.**—Damage estimated at between $8,000 and $10,000 was caused to the plant of the Pittsburgh & Des Moines Steel Co. by fire which broke out on Sunday morning in the engine room at the plant. Heavy damage was done to the building and machinery. The roof at the west end of the building was demolished and the engine room was transformed into a mass of debris. The plant was formerly owned by the Chatham Bridge Co. and was recently taken over by the Pittsburgh & Des Moines Steel Co. as a Canadian branch.

**Niagara Falls, Ont.**—The Hydro-electric Power Commission of Ontario are going ahead with the construction of a new pipe line at Niagara Falls, running from the intake to the generating station, and paralleling those now in operation. It is expected this line will be completed by July, by which time also it is the intention to have extra turbine and generating equipment to the extent of some 25,000 h.p. ready for operation. Whether this will be in the form of two units similar to the latest additions to this power house, or whether one large unit will be installed, has not yet been determined.

**London, Ont.**—Sir Adam Beck announced here on Monday that he had awarded contracts for the construction of a 13½-foot wood stave flume with [illegible] for the development of an additional block of 50,000 horse-power at the plant of the Ontario Power Co. at Niagara Falls. Of this additional horse-power 20,000 will be available in August next and the remainder in October. It is estimated that it will next winter save the importation of more than three-quarters of a million tons of soft coal, which at from $8 to $10 a ton would represent an outlay of from $6,000,000 to $7,500,000.

## GENERAL

**Sydney, N.S.**—An explosion at the Cross Fertilizer Works on Dec. 30 started a fire which destroyed the main building.

**Quebec, Que.**—Price Bros. announce the closing down of their pulp mill at Kenogami owing to the shortage of cars.

## BUILDING

**Montreal, Que.**—Fire on Jan. 1 destroyed the Arena, St. Catherine West and Wood Ave. The loss is estimated at approximately $150,000, with $50,000 insurance. It may not be rebuilt.

**Toronto, Ont.**—The T. Eaton Co. are going ahead with their new mail order building on Harbor Square. The plans have been prepared for a building 200 feet by 400 feet, with an estimated cost of about $1,000,000, and the work of construction will start as soon as the weather permits.

**St. John, N.B.**—Fire on Jan. 2 destroyed a three-storey brick building and a three-storey wooden building, 459 to 463 Main Street, owned and occupied by Hamm Brothers, biscuit and confectionery manufacturers. The cause of the fire is unknown. The loss is estimated at from $75,000 to $100,000 largely covered by insurance.

**Ottawa, Ont.**—The Halifax Reconstruction Committee has accepted plans prepared by the Commission on Conservation for terrace-cottage types of dwellings for temporary homes for 1,500 families of that city. Thos. Adams is town-planning advisor of the Commission of Conservation. R. A. Robb, architect, prepared the sketches.

## MUNICIPAL

**Alliston, Ont.**—The Town Council propose electrifying the municipal pumping plant if the by-law passes.

**Toronto, Ont.**—The townships of Scarborough and Etobicoke propose to instal water distribution systems.

**Sherbrooke, Que.**—The City Council will build a dam at the civic power station and make permanent improvements at both power stations.

**Armagh, Que.**—Plans have been drawn for the town council for waterworks costing $40,000. Engineers, Gouvin and Beauchemin, Quebec, Que

**Burton Township, Ont.**—The Township Council propose spending $55,000 on the purchase of necessary material and equipment for instaling an electric light system.

**Sault Ste. Marie, Ont.**—The city of Sault Ste. Marie and town of Steelton merged into one municipality on New Year's Day, retaining the name of this city. On September 25 last the ratepayers of both municipalities voted in favor of amalgamation.

**Mimico, Ont.**—The council going in by acclamation left the only voting at Mimico in connection with a by-law to appoint a commission to take over the public utilities, the waterworks system and the Hydro. The by-law carried with a large majority. The members of the commission will not be voted on until next year.

**Oshawa, Ont.**—The Thornton Rubber Co. are acquiring the property formerly owned by the Ontario Malleable Steel Range Co. and will instal machinery for manufacturing rubberized textile goods. The company has an authorized capital of $45,000, all of which is to be invested in plant and machinery, and in addition to this a sum of from $10,000 to $15,000 is to be provided by two of the partners. The company is to have a fixed assessment for ten years of $5,000 per annum, and at the end of that time a cash bonus of $10,000 is to be paid by the town if the company has carried out all its agreements. The Town Council has appointed a committee to complete negotiations up to the point of submitting the by-law to the electorate.

**Windsor, Ont.**—The Essex Border Utilities Commission at a protracted session finally reached a complete understanding in the matter of an equitable apportionment of the cost of constructing a temporary sewerage system, which will discharge at a point below the Windsor and Walkerville water main intake pipes. The new arrangement means that Windsor will contribute $28,000 towards the cost of the new work, Walkerville $18,000, Ford $67,000, Sandwich $25,333.33, Sandwich West $28,333.33, and Ojibway $46,533.333. The assessments announced will now have to be submitted to the Councils of the various municipalities for ratification before going to the Ontario Railway and Municipal Board for final approval.

## PERSONAL

**H. D. Reid** has been appointed president of the Reid Newfoundland Railway in succession to Sir William D. Reid, who has resigned.

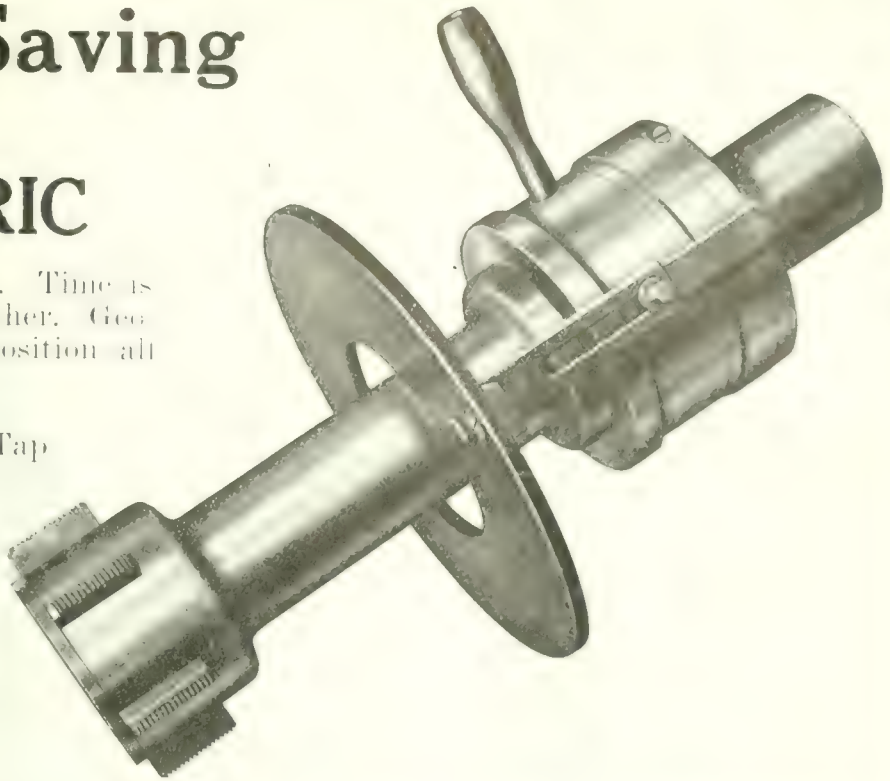
**J. D. Cumming,** formerly with the Canadian Copper Co., Copper Cliff, Ont., has accepted the position of assistant to

# Daylight Saving
## with a
# GEOMETRIC

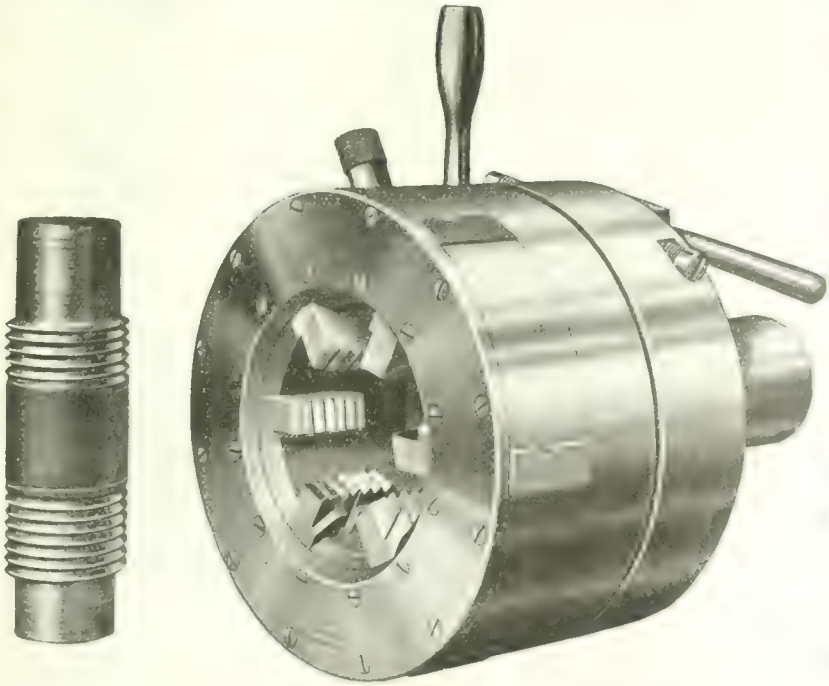
That is what it amounts to. Time is not the only thing saved, either. Geometrics are a saving proposition all around.

This Geometric Collapsing Tap is specially arranged for deep tapping in Projectile Caps.

All classes of thread tapping above 3¼-inch diameter are taken care of by Geometric Collapsing Taps.



***Twenty-five years of specializing in Screw Thread Cutting Tools has made the name GEOMETRIC stand for all that could be asked in Screw Thread Production.***



When it is an outside thread, Geometric Die Heads cut every style from 1/16-inch size up to greatest required diameter.

A U.S. Navy Yard is using this 4½-inch size Style "D" Geometric Die Head. United States Navy Yards accept no second quality.

Do your Screw Machines and Turret Lathes swing Geometrics?

You have as much right to Geometric benefits as any other manufacturer.

## The Geometric Tool Company, New Haven, Conn., U.S.A.

*Canadian Agents:*

**Williams & Wilson, Limited, Montreal. The A. R. Williams Machinery Company, Limited, Toronto, Winnipeg, St. John, N.B.**

works manager of the Westmount plant of P. Lyall & Sons Construction Co., Montreal.

**Robert Law Benson**, assistant city engineer of St. Boniface, Man., died at his home on Jan. 2, at the age of 53 years. Mr. Benson was a native of Hamilton, Ont., and had been in the Winnipeg vicinity nine years.

**Frederick Triebel** died at Montreal on Jan. 1. Mr. Triebel, who was born at Cohoes, N.Y., 67 years ago, came to Montreal and entered the service of the Ogilvie Flour Mills, where he was head mill wright for twelve years. He was also for thirteen years mechanical engineer for the Canadian Rubber Co.

**C. M. Carmichael**, formerly assistant works manager in charge of the electric furnace department of the Anniston Steel Co., Anniston, Ala., and later with the British Forgings, Ltd., Toronto, Ont., as superintendent of the steel plant, has accepted the position of assistant works manager, Electro Metals Co., Welland, Ont.

**William Earle, C. E.**, died last Saturday at the residence of his father-in-law, Senator Domville of Rothesay, near St. John, N.B. He had done engineering work with the C.P.R., was former manager of the St. John Street Railway, and latterly was District Engineer of Dominion Public Works in Manitoba.

**J. C. Broadnax**, who was connected with the electric furnace department of the Anniston Steel Co., Anniston, Ala., and more recently with the British Forgings, Ltd., Toronto, Ont., as assistant superintendent of the steel plant, has been appointed superintendent of the electric furnace department at the Watertown Arsenal, Watertown, Mass.

**John Henry Helm** died at Port Hope, Ont., on Sunday, after a brief illness. Mr. Helm was born in Cobourg in 1845, and was educated at Victoria College. When quite a young man he moved to Port Hope, and was engaged in the foundry and machine business with his father, the late John Helm, taking over the same when the latter retired.

## TRADE GOSSIP

**Galt Customs Collections.**—Customs Collector Peck announced that the returns for December were $14,858 less than for the same month last year, the total being $37,197. Smaller importations of coal, iron, wool and steel account for the decrease.

**Lake Superior Mines Ready for Big Season.**—Authorities say that mines in the Lake Superior district will be in position to produce and ship 70,000,000 tons of iron ore during the 1918 season. This would compare with a high record of 64,734,198 tons of ore shipped in the 1916 season.

**The Steel Company of Canada** will hold the annual general sales conference at Hamilton on Jan. 15 to 18 inclusive which will be attended by the entire sales force from Halifax to Vancouver. A feature of this conference will be a series of interesting papers read by various members of the staff, followed by discussions.

**The A. R. Williams Machinery Co.** have purchased the patterns, drawings and manufacturing rights of the "Montreal" rough turning and boring lathe. The machine has in the past been manufactured by the Montreal Foundry & Machine Co., at Montreal, Que., and has made quite a reputation among munition manufacturers on 6-inch shells.

**Trail Smelter Working.**—The Trail smelter is again operating and several hundred men have returned to work, the blast furnace is running as usual. A number of mines which are controlled by the Consolidated Co. are also making arrangements to re-open, while those mines which were shipping their zinc ores to the south will now have an outlet closer home.

**B. O. T. Journal.**—The St. John, N.B., Board of Trade has recently issued the December number of their journal which contains as usual a fund of interesting matter relative to the Port of St. John and to the province of New Brunswick generally. The journal features the strategic value of the port of St. John as a factor in the successful prosecution of the war and also in the industrial development in Canada.

**Toronto Fire Loss Decrease for 1917.**—The fire loss in Toronto for the year 1917 is estimated at $1,164,965, which is over $300,000 less than that estimated for the year previously. For the month of December the loss was given as over $200,000. The fire losses by months for 1917 are as follows:—January, $79,183; February, $103,399; March, $67,309; April, $42,501; May, $349,737; June, $6,284; July, $5,861; August, $16,376; September, $65,578; October, $35,975; November, $177,316; December, $214,946.

**The Jenckes Machine Co.** of Sherbrooke, Que., has secured large additional contracts, which will involve the employment of several hundred more men. Additional capital has been brought into the business through those interests which are identified with the Canadian Ingersoll Rand Co., another of Sherbrooke's large industries. At a recent meeting of shareholders of the Jenckes Machine Co. some changes were made in the personnel of the board, George Doubleday, of New York, becoming the new president, and E. W. Gilman, general manager.

**To Relieve Traffic Congestion.**—The Canadian Railway Board has stationed a traffic expert at the Niagara Frontier to supervise and expedite the movement of coal and other traffic, so that the freight each day is divided up among all the Canadian railways, irrespective of how the cars may have been routed. This is a precautionary step to make absolutely certain that the full capacity of the Canadian roads is used so as to prevent any possible congestion. Another order was made by which all the railway ferries plying between Detroit and Windsor will be pooled.

**Will Expedite Coal Shipments to Canada.**—C. A. Magrath, Dominion Fuel Controller, who has been in Washington and New York for some days in connection with the fuel situation, has succeeded in arranging for a number of emergency shipments of coal to Canada. This has been done despite the pressure coming from the consumers in the United States to limit the exportation from the country in order to relieve the acute situation across the border. While there is a shortage of coal in some districts, there must be a large supply in the country and the problem is largely one of transportation and distribution. This is accentuated both in connection with distribution in Canada and additional shipments from across the line, by war conditions.

## MARINE

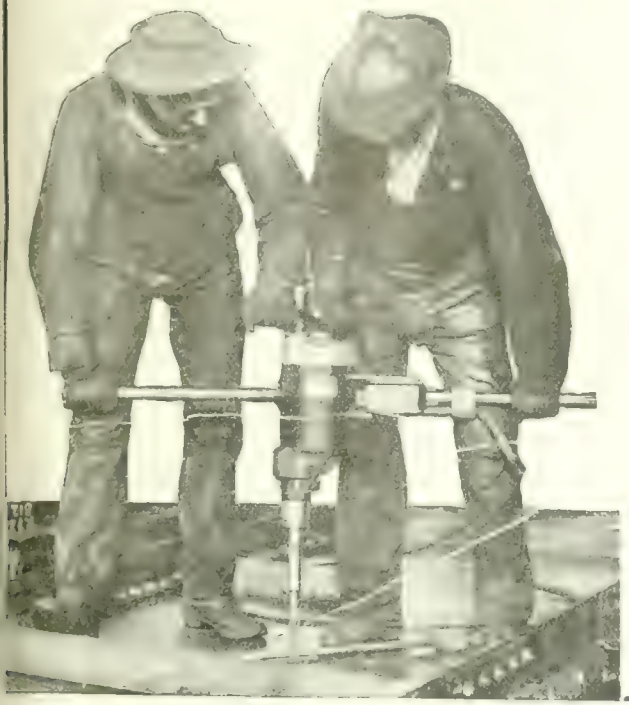
**Sarnia, Ont.**—Word has been received in this city that the Reid Wrecking and Towing Co. has received a contract to salvage the large steamer Curaca, which is sunk in the harbor at Halifax as a result of the recent explosion. Capt. J. T. Reid confirmed the report, and stated that this concern was shipping the outfit for the salvaging work. Wrecking operations will begin as soon as pumps and crews arrive at the scene.

**Victoria, B.C.**—The schooner Mary Barnard, which is now on the way to the Antipodes, is not equipped with engines, their arrival being delayed so long that the company decided to wait no longer, but to let the vessel make the passage as a straight windjammer. The Janet Carruthers left as an auxiliary schooner, but the engines gave trouble and she had to put into Honolulu recently, where the engines were disconnected and it proceeded under sail alone, calling at Samoa. The ship is now due at her destination any day.

**Victoria, B.C.**—The schooners Beatrice Castle and Jean Steedman, the last two vessels to be completed by the Cameron-Genoa Mills Co. to the order of the Canada West Coast Navigation Co., are still at the wharves in the inner harbor, being installed with semi-diesel Bolinder auxiliary engines, which recently arrived from Sweden. It was stated a few days ago that the work will probably be completed on both vessels by January 20, on or about which date they will go on berth to load lumber for offshore points. The Beatrice Castle will get its cargo at the Genoa Bay mills. Its destination is so far uncertain, but it will probably be either Adelaide or Sydney, Australia, while the Jean Steedman, after taking on timber at Chemainus, will clear for Sydney, Australia.

**Victoria, B.C.**—According to news received in Victoria recently, the auxiliary wooden schooner Mabel Stewart, one of the later vessels launched last summer at the North Vancouver plant of the Wallace Shipyards, arrived at Port Adelaide on December 20 with lumber from Genoa Bay and the Terminal City. The ship was under command of Captain Robinson, and made the voyage in the comparatively fast time of sixty-three days. The Mabel Stewart, which is the tenth vessel of the fleet of twelve built for the Canada West Coast Navigation Co. by British Columbia shipyards, was

They stay on the job so much longer and they work so much faster that they actually reduce manufacturing expense and labor costs from 25 to 80 per cent.



Van Dorn ELECTRIC TOOLS

Portable Electric DRILLS

Drill through anything of any size from 3-16 to 2 inches.

They're built by men who have spent 14 years manufacturing portable electric tools exclusively. They're built as an electric tool must be, to stand up to severe service indoors or out, and stay out of the repair shop.

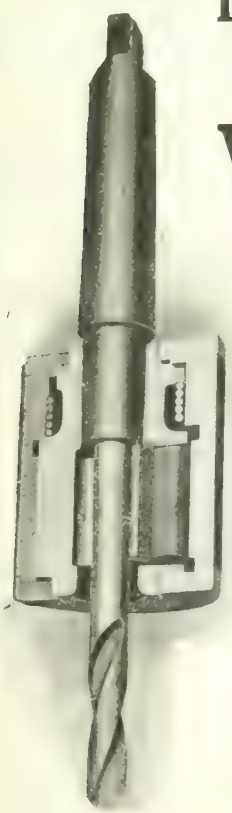
Van Dorn electric way is the cleanest, speediest and most economical. Write:

Aikenhead's

17, 19, 21 TEMPERANCE STREET
TORONTO - CANADA

Look at the Jaw Construction of This

WAHLSTROM Chuck



The cam action is such that the harder the jaws grip the shank.

The New Wahlstrom is the perfected Automatic Chuck famed for durability and the time and labor that it saves. It self-centers the tool, enabling the operator, while spindle is running, to change tools in two seconds.

Beyond doubt the strongest, quickest Automatic Chuck for drilling, reaming, counterboring and tapping is this New Wahlstrom. For all the interesting particulars write.

Even though old drills with broken tangs be used, the grip of this New Wahlstrom is always positive. Made in two styles —one for straight shank tools, the other for M.T. shank tools.

Aikenhead's

17, 19, 21 Temperance St., Toronto, Canada

launched at North Vancouver on August 11 and is equipped with auxiliary engines. It loaded 1,250,000 feet of lumber at the government dock in Vancouver and left there on October 11 for Genoa Bay to complete, clearing for Australia a week later.

# INCORPORATIONS

**H. Gray & Co.** has been incorporated at Ottawa with a capital of $150,000 to manufacture mill supplies, cotton waste, greases, etc., The head office is at Montreal and the incorporators are E. E. Howard, J. DeWitt and E. A. Rose, all of Montreal.

**Beaver Truck & Tractors Ltd.** has been incorporated at Ottawa by E. P. Brownell of Toronto, also C. J. Stodgell and H. P. Crocker of Walkerville, Ont., to manufacture tractors, motor trucks, aeroplanes, etc., at Walkerville, Ont., with capital of $500,000.

**Canadian Kodak Co.** has been incorporated at Ottawa with a capital of $5,000,000 to take over as a going concern the Canadian Kodak, an Ontario corporation, manufacturers of photographic supplies of all kinds. The factory is at Mount Dennis, near Toronto.

**Toronto Hardware Mfg. Co.** has been incorporated at Ottawa with a capital of $400,000 to carry on the business of manufacturers, ironfounders, boilermakers, machinists and mechanical engineers at Toronto. The incorporators are A. W. Langmuir, W. A. J. Case and W. M. Smith, all of Toronto, Ont.

# CONTRACTS

**Toronto, Ont.**—The contract for a new boiler house for the Swift Canadian Co., operate a faction in Toronto. Although Construction Co.

**Copper Cliff, Ont.**—The Canadian Copper Co. have let the contracts for a new converter and building to the Allis-Chalmers Co. and the Dominion Bridge Co. respectively.

**St. John, N.B.**—The contract for the boilers, piping, pumps and valves, etc., for the General Public Hospital has been let to F. S. Walker of this city, the contract price being $38,500.

**Toronto, Ont.**—Bennet & Wright, Ltd., have been awarded the contract for the heating and plumbing installations for the new addition which the Canadian Aeroplane Co. are building to their factory on Dufferin Street.

# TENDERS

**Stony Point, Ont.**—Tenders will be received by the undersigned up to January 15, 1918, for the sale of the plant of the Stony Point Canning Co., capacity 25,000 to 30,000 cases. John Watson, Inspector, Stony Point, Ont.

# RAILWAYS

**Chatham, Ont.**—Electrification of a section of the Chatham-Wallaceburg division of the C., W. and L. E., with the use of [illegible] current, is undertaken, and it is expected that [illegible] will be moved by the spring from Niagara for the first time shortly. Because of the shortage of fuel the company has found it impossible to generate sufficient power for the entire system, which reaches from Erie Beach to Wallaceburg.

# CATALOGUES

**Woodworking Lathe.**—Bulletin illustrating and describing No. 56 motor-driven speed lathe made by the Oliver Machinery Co., Grand Rapids, Mich. A complete specification covers the leading and other features of this lathe while particulars are also given of the attachments.

**The Unseen Loss** is the title of a folder recently isued by the Armstrong Cork Co., Pittsburgh, Pa., dealing with the "Nonpareil" cork covering for refrigeration plants. Copies of this folder have been sent to all owners of refrigerating machines in Canada and the United States. The company, however, will be glad to send a copy to any firm who has not received one if they will make application in writing.

**Drilling and Tapping Machines.**—The Langelier Manufacturing Co., Providence, R.I., have issued a new catalogue describing plain bearing belt and motor-driven drilling and tapping machines for general manufacturing use. A full line of machines for a large variety of purposes is dealt with in this catalogue, each machine being illustrated together with specifications giving full particulars of each type. A telegraphic code is included with each machine. A useful feature in the catalogue consists of a series of important notes for the guidance of inquirers and purchasers. The catalogue also describes a line of special precision machines for extra fine drilling. This is a well gotten up catalogue, both the illustrations and reading matter being well arranged.

## CANADA'S COAL PROBLEM

The *Monetary Times* this week publishes a four-page article by Arthur V. White on "Canada's Coal Problem." Mr. White is consulting engineer to the Conservation Commission, and has filled many important engineering appointments in Europe and America.

Canada at present imports annually from the United States 4,500,000 tons of anthracite and from ten to fourteen million tons of bituminous coal, the latter largely for power purposes. It is believed that the American anthracite fields—even at the pre-war rate of production—will be exhausted in a hundred years. The friendliness of the United States towards this country has recently been emphasized in this very question of the coal supply, but circumstances are conceivable in which our neighbor to the south might feel compelled, in the interests of her own population, to completely shut off the export of anthracite, and to barter her bituminous output for particularly necessary Canadian products, such as electrical power.

Canada now exports to the United States about 275,000 horse-power of electrical energy, which Mr. White calculates as equal to three million tons of coal, and goes on to estimate the developed electrical horse-power of Canada at 1,813,200, and the possible horse-power at 18,800,000. But by no means all of our water powers, he says, may be economically developed. He calls attention to the importance of conserving all of this horse-power and turning it to public uses.

## BUILDING SITUATION AT LETHBRIDGE

OWING to the high cost of materials and scarcity of labor there have not been many buildings erected at Lethbridge, Alta., this year, although the figures show an improvement over last year. The permits for 1916 were valued at $79,227, and for 1917, $94,628, in both cases up to the end of November. For both these years the work has been almost exclusively additions to existing buildings, but two new garages and two or three small business blocks have been built as well as a few residences. The shortage of accommodation as regards residences caused a few people to build. In addition to the above the City of Lethbridge has constructed a new water filtration plant, Robert's system, at a cost of $100,000.00. No great amount of activity is expected during 1918 owing to the excessive cost of building operations, although residences are still scarce.

## TRADE ENQUIRIES

THE following trade enquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained on application to the Department.

1605. **Chemicals, colors, etc.**—A young man at Genoa would represent on commission manufacturers of chemicals, colors, etc., g.f.m.b.

1609. **Beltings, lubricant, engineering articles in general, small machinery, machine tools, ironmongery, steel, household articles, etc.**—A travelling representative would take up agencies for Italy and colonies for the foregoing a.g.v.

1611. **Machinery for steel works and rolling mills, machine tools for large engineering and shipbuilding works.**—An engineering office at Genoa would import for its own account or on commission the above-mentioned articles, g.f.s.a.

1616. **Iron bars (round and square), iron water and gas pipes, steel plates.**—An agent at Rome wishes to represent manufacturers of the foregoing articles, r.p.c.

1604. **Flexible metallic tubes for gas and accoustic purposes.**—A Taranto company wishes to import the above, t.g. s.l.p.

1618. **Bronze and aluminium powder.**—An agent in Turin is desirous of getting in touch with Canadian exporters of bronze and aluminium powder.

1619. **Saws, screws, files and nails.**—A house in Naples which furnishes the Royal Arsenals of Artillery and Marine

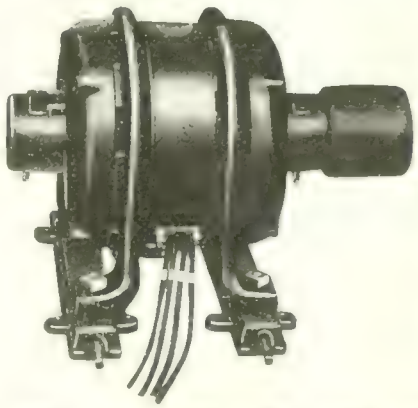
# USE Aikenhead's "AK" Motors

The quietest running motor on the market today is the "A.K." —a constant speed induction motor in 2 or 3 phase, 25, 30 and 60 cycles

Manufactured by the North Western Electric Company, of Chicago. Service beyond your highest expectations is warranted by this name

Aikenhead's carry the following "A.K." Motors in stock: 25 cycle in 1, 2, 3, 5 and 7½ H.P.: 1470 R.P.M.: 25 cycle in 1, 2, 3 and 5 H.P.: 735 R.P.M

*Write us for "A.K." Motor Facts.*



**Aikenhead Hardware Limited**

**17, 19, 21 Temperance Street TORONTO, CAN.**

# METAL STAMPINGS

We are manufacturers of stamped parts for other manufacturers.

We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.

We can finish steel stamping in Nickel, Brass or Copper.

**Send us a sample order.**

1625. **Chemicals.**—A merchant and agent in Genoa handling chemical products such as sal-ammoniac, sulphate of soda, sulphate of copper, etc., is anxious to receive supplies from Canada.

1622. **Corundum.**—A firm in Turin asks for corundum from Canada.

1625. **Machinery for working wood and metals, saws (band and circular), files, etc.**—A Genoese house of agents would like to hear from Canadian manufacturers who are prepared either now or after the war to export to Italy all kinds of machinery and machine tools for working wood and metals, wood saws, band and circular, carpenters' planes, circular saws for iron, files, metals in sheets, bars and tubes and chemical products for industrial purposes.

1629. **Asbestos.**—A large importing house in Milan and Genoa with Canadian references will be pleased to negotiate with Canadian shippers of asbestos.

1630. **Mica and asbestos.**—A Genoese firm which handles metals, raw materials, chemicals, etc., would be pleased to place orders in Canada for mica and asbestos.

1631. **High-speed steel, saws, helices, mandrels, etc.**—A house of merchants and agents in Genoa requires high-speed steel, saws for metals, chisels of high-speed steel, helices, mandrels and band saws of every dimension.

1633. **Hardware, agricultural instruments and kitchenware.**—An old-established house in Milan, with travelling representatives in Italy, is desirous of getting in touch with Canadian manufacturers who handle agricultural instruments such as garden rakes, spades, shovels, scythes, also files and drills and general hardware products and kitchen utensils.

1640. **Wire nails.**—A Northampton firm is open to purchase wire nails.

## LACHINE CANAL TRAFFIC

STATISTICS available as to the freight shipped through the Lachine Canal for the season of 1917 show that 607 vessels made 7,936 trips this season of 294,773 tons. 1916 totalled 585 vessels 278,760 tons burthen with the vessels making 7,579 trips through the canal. In the year just closed there were more than 70,000 tons of grain and other merchandise, shipped above the amount in 1916. Of wheat there were 13,201,732 bushels, an increase of over 2,000,000 bushels.

There were 265,411 more tons of coal; 8,000 more cords of pulpwood; 24,000 more tons of pulp; 85,000 more sacks of flour; 38,000 more tons of sand and 165 more cargoes through the canal. The passenger list for the season totalled 69,910, a slight increase over 1916 figures. The total combined tonnage of all the ships through the canal amounted to 4,145,836 tons an increase of 144,663 tons. The cargo tonnage was 70,000 more than that the previous season's figures.

There was a big decrease in all grains with the exception of wheat. In corn, oats, barley, rye and flaxseed, the season of 1917 showed a falling off of 5,518,100 bushels. There were cargoes 25,168,452 in 1916, and 19,350,352, in 1917. Eggs, butter, cheese and apples, all showed big decrease in 1917. Flour of which, there was none shipped last year, passed through the canal this season in 85,800 sacks. In lumber there has been a decrease of 1,289,400 feet board measure brought down from Ottawa for United States ports by American canal boats.

## PUMPS WANTED IN FRANCE

THE "Official Bulletin" of the United States Government announces that the following cablegram has just been received from the Paris headquarters of the American Red Cross:—

"'Send us pumps,' is an appeal to-day from a Red Cross delegate in the devastated area. The retreating Germans left little untouched there last spring. Spokes were cut from wheels of farm carts, orchards were felled, farmhouses wrecked. In many cases pumps were destroyed, wells filled with rubbish and polluted.

"Of the few men and women who have managed to filter back to live in the one good corner of their wrecked buildings, to clear the fields of barbed wire and try to till them, none dares drink from the old wells which they had depended on all their lives unless they bear a sign reading 'Good water,' to show that they have been purified.

"To these safe wells people come from far and near with their jugs and pails. To make their already difficult life a little easier and to make it possible for more of them to come back to their devastated fields—all they have—as soon as pumps can be brought, ten will be sent to fill the need for them in this district. It is a real though slight contribution to the giant task of reconstruction."

## RAILWAY CARS BEING RETURNED

THE new centralized management of the United States railroads, with its pooling arrangement of rolling stock and economies of routing and motive power, is already helping to solve one of the main problems of the Canadian Railway Companies, namely, the more prompt return of Canadian rolling stock routed to United States points. Rolling stock shortage in Canada has been aggravated to a large extent by the delays in securing return of cars from the United States roads. Thousands of Candian box cars, coal cars, etc., have been kept across the line for months. The shortage of cars in the United States, the keenness of railway competition, and the lack of any central co-ordinating management, have

made the tracing and return of cars to Canada very difficult for a considerable time past. The Canadian Railway War Board is now taking advantage of the new United States system, and a general scheme is being worked out looking to reciprocal action for prompt return of cars, and the most economic methods of conserving and utilizing present rolling stock resources.

### CANADA'S WAR ORDERS

WAR orders valued at approximately $1,812,000,000 have been placed in Canada since the outbreak of war. This total has been arrived at by "The Monetary Times" as the result of three successive investigations and with the assistance of figures supplied by the Imperial Munitions Board, the British War Office Service in Canada, the Department of Agriculture, the Department of Trade and Commerce and the War Purchasing Commission, Ottawa. This vast sum represents an average annual expenditure in Canada of $604,000,000 on shells and general war supplies for three years of war, as little was supplied by us before the end of 1914.

More than half the orders received are represented by munitions. Since the outbreak of war to the end of September last, the orders placed by the Imperial Munitions Board were valued at $925,270,000. Since that date, approximately $75,000,000 of further orders have been placed, bringing the total value of munitions orders up to $1,000,270,000, to the end of 1917. In addition, shipbuilding orders of over $46,000,000 have been placed here.

### WILL INVESTIGATE GAS PROBLEM

THE serious condition existing throughout South-Western Ontario as a result of the shortage of natural gas is to be investigated at once by the Ontario Railway and Municipal Board. The board will be asked to enquire into a number of things that are causing a great deal of ill-feeling and controversy in the district. On one hand it is charged that the producing companies are not producing up to capacity in order to further plans for getting new contracts at higher rates. Another complaint is that while some municipalities are getting an adequate supply of gas others, in which contract prices are lower, are going without.

"Though this is regarded in civil life as a trivial matter in the army it is a very, very serious thing. I can quite understand you—a recruit—not realizing that, but I am obliged to punish you. However, I will be lenient with you. Seven days' C.B. And," continued the O.C. advisingly, "in future ply the game! Be a sport, Atkins! I am!"

"You are, sir?" queried Tommy, apparently amazed.

"Yes, I am," replied the O.C., waxing indignant.

"Well, then, sir," said Tommy earnestly "I'll toss you, fourteen days or nothing!"

# Notes Regarding Preparatory Work in Shell Production

By M. H. Potter

*A good start is half the battle and if more shell [illegible] preparatory work would be done very differently. Much waste effort was doubtless due to inexperience and urgency of requirements, but the advisability of thoroughly co-ordinated effort is fully recognized by successful producers. The writer's description of such work is timely and of proven interest.*

THIS article has been written in hope that the ideas will be of use to those who are confronted with similar problems or may undertake shell manufacturing in the future.

The problem for equipping for this work is in no way different from equipping for the manufacturing of any other machined article required in large quantities. While there is considerable rush required the various operations are comparatively few and not complicated.

### Executives Formulate Plans and Decide on Gauge Equipment

A conference was called of the heads of the departments, namely, the factory superintendent, the superintendent of equipment, the chief tool designer and the chief inspector. The planning of the sequence of operations, the methods of tooling, the system of gauging and the nature of the machine tool equipment was talked over and a preliminary decision reached.

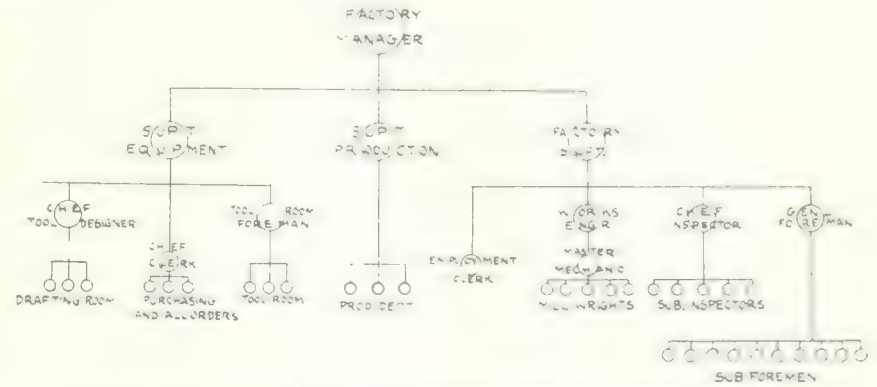
The superintendent of equipment with the aid of the chief tool designer fixed the design of the tools, jigs, fixtures and special labor-saving devices which enabled the drafting room to proceed. All designs, before being despatched to the toolroom, were finally approved by the factory superintendent. Consultation with the general foreman was necessitated in many instances as it was the idea of the factory manager that the design of special equipment should be passed upon by the executive who was to actually supervise the use of same.

Another conference was called, the superintendent of equipment, the chief inspector and chief tool designer taking part. The type and design of the gauges were determined. While this work was under way, the superintendent of production and a tool designer visited a number of the larger shell plants. All the assistance possible was sought. Upon their return another general conference was called, all the information gathered was presented and it was decided that certain changes would be made to conform to what the visited manufacturers were doing; that no experimenting would be done until production was partly under way.

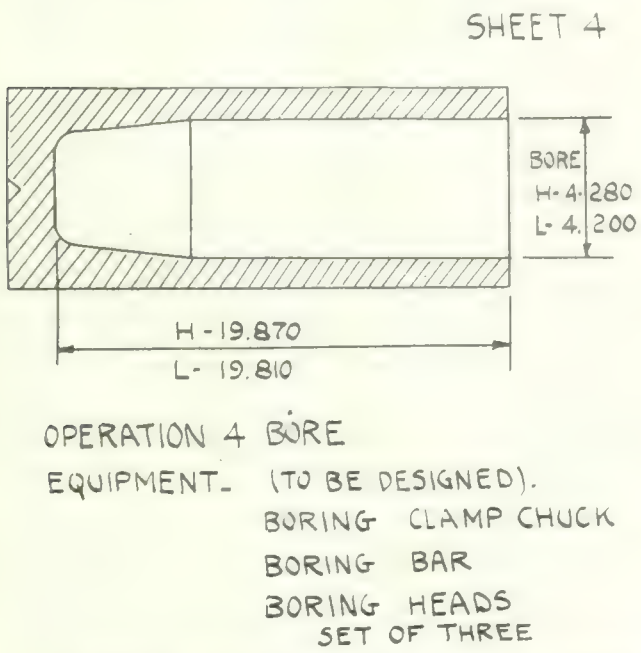
### Preliminary Steps Before Starting Production

From the decisions already arrived at the drafting department issued blue prints in booklet form of the sequence, one sheet being devoted to each operation and one to each gauging, operation 4 being illustrated herewith.

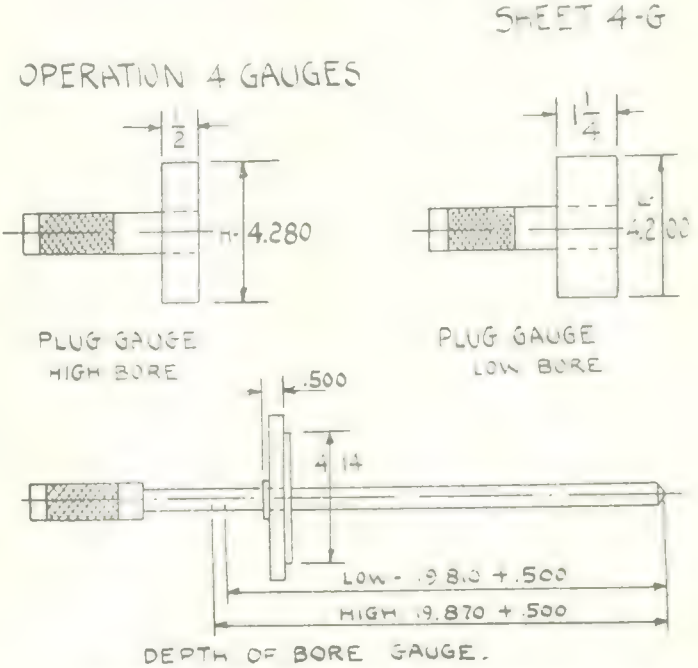
As the designs for the special tool equipment were approved and issued they were sent to the tool room, one only being ordered. When each component of equipment was installed the employment department hired the necessary operators. Necessary alterations were



ORGANIZATION DIAGRAM SHOWING DISTRIBUTION OF DUTIES AND RELATIONS OF VARIOUS DEPARTMENTS.



INDIVIDUAL OPERATION SHEET SHOWING DIMENSIONS AND EQUIPMENT.



INDIVIDUAL GAUGE SHEET SHOWING GAUGES REQUIRED FOR OPERATION 4.

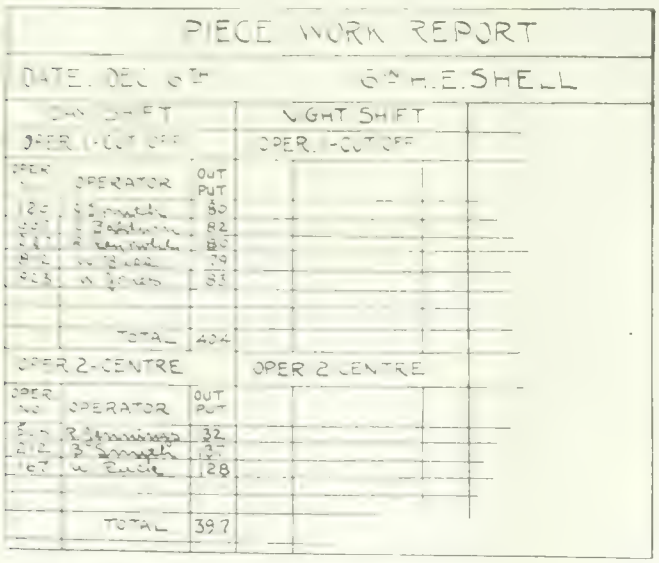
made in the designs by the drafting department and an order was then issued for the number required to equip each machine.

The first six shell forgings were closely inspected, the weights being taken after each operation. This precaution was necessary and furnished valuable data, it prevented light or heavy shells.

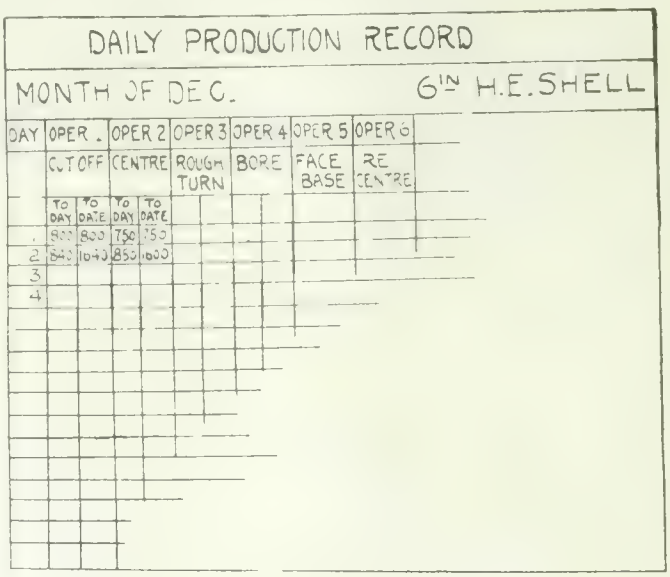
Special attention is called to the organization diagram; this is most important. It will be noted that the ordering and inspection department come under the direct supervision of the superintendent of equipment. He was therefore in a position to know exactly what was ordered, also when it was in place on the job.

### Speeding Up Production

After production was under way considerable trouble was experienced as follows: (1) The inspection following each operation, so as to insure the work being within the required limits. The prevailing method used was that should the work of any particular operation fail to pass either shop or government inspection that the operation must be halted at once. Under no conditions was work resumed until the general foreman and chief inspector located the fault. This precaution eliminated the necessity of subsequent rectification and prevented the possibility of general confusion in the shop. (2) The keeping of the necessary records to enable those in charge to know exactly how the work was proceeding. After considerable study and thought the production department issued a daily production sheet. (3) As the required production was reached the operators were placed on a piece work basis. No order to have a positive record and check of each operator's output a piece work report was maintained by the production department.



REPORT SHOWING PIECEWORK OUTPUT OF EACH OPERATOR AND OPERATION.



RECORD SHOWING DAILY TOTAL AND TOTAL TO DATE OF EACH OPERATION

—⚙—

Harry Bayne, Controller of Metals, has gone to Washington to discuss with American authorities the supply in the United States available for Canadian manufacturers.

## BRITISH PRACTICE IN WIRE-DRAWING*

By A. T. Adam.

IT is difficult to define clearly what a wire rod is, because plants are now in operation which are drawing or rolling cold bars in round, square or hexagon, etc., up to 2½ in. in diameter at least, probably more. In speaking of a wire rod, however, one generally means material which has been rolled hot to about ½ in. diameter and under.

### Necessity for Pickling

Before the rods can be drawn through a die they must be freed entirely from scale of oxide, otherwise the hole through which the wire is drawn will be torn out. The rods are, therefore, pickled in sulphuric or hydrochloric acid. When the coils are dipped in the pickling tank, it is usual to have a solution, containing anything from 2 to 8 per cent. of free acid, in which case the operation of cleaning takes about two hours. Slow cleaning is almost essential when the gauge of the wire is small. A strong solution can be used when the gauge is large or when the wire is drawn through the bath continuously instead of being dipped in the form of a coil.

The process of picking may be hastened by using a hot bath. The acid bath works best when it has been in operation a few days, or when the specific gravity has been increased by sulphate or chloride of iron. If the specific gravity be too high, however, the cleaning action will cease unless heat is used. Mr. Adam has found the percentage of free acid in a spent tank as high as in a freshly made up tank. The specific gravity of the former was 1.28 and of the latter 1.03. Mechanical means have been tried to assist the acid in cleaning the higher class wires, but without much success. This is unfortunate because acid is apt to make the wire brittle unless great care is taken to remove it completely.

### Washing

When all the scale has been removed from the wire it is thoroughly washed with water from a hose. The cheaper qualities of wire are then dipped in hot lime and dried, but with the higher grade wires, which have to receive several passes through the draw plate without annealing, it is necessary to give them a water coat. This is done by keeping the coils continuously under a spray of water until a brown rust is formed. During this operation they must not be allowed to become dry. The wire is limed to neutralize any acid remaining and to prevent corrosion. The coil is dried in a blueing oven at 100 deg. C., when the last traces of acid should be driven off. The wire is then ready for cold drawing. The cleaning operation has to be performed not only on the raw wire rod, but also on the drawn wire, each time it has been annealed to facilitate further drawing.

### Drawing

In drawing, the reduction effected at each pass through the die varies from 5 per cent. to 20 per cent. of the diameter, according to the nature of the material. The draw plates are made from self-hardening steels.

Some of the alloy steels are used nowadays for draw plates of special make; for example, one well-known make contains 14 per cent. chromium and 3 per cent. carbon. These elements form a very hard double carbide with the iron. The hole in the draw plate through which the wire passes is first punched hot, then sized and shaped correctly, when cold, with hardened and tempered tapered punches. Very fine wires are drawn through jeweled dies, diamonds and rubies being chiefly used. Before the wire enters the die it passes through tallow or olive oil soap, which acts as a lubricant.

Some wires are drawn wet, in which case a liquid lubricant is used. Various secret lubricants are in vogue for the wet process, sour beer being a favorite ingredient of most of them. When the wire is to be drawn wet it is polished to give a bright metallic surface, and is then

*Abstract of paper read before Edinburgh Section of the Society of Chemical Industry.

coated with copper by immersion in a bath of copper sulphate. The copper being softer than the steel, forms a kind of cushion between it and the die. It is drawn into the wire and gives it a yellow color. The process of drawing is repeated until the wire is finished or too hard to be drawn further without heat treatment.

### BRIEF SURVEY OF U. S. BUSINESS CONDITIONS

American business closed a difficult year with optimistic hopes for 1918. Manufacturers of essentials are far behind orders. Lumber mills and coal mines are operating to capacity.

New industries and expansions due to the war particularly in shipbuilding have opened new gates of employment while of out-of-works there is the smallest number in years.

With higher wages the country's buying power has increased tremendously so that business generally looks to the future with confidence. Drastic economy shown by the purchasing public has merely resulted in placing merchandising on a stable foundation while government regulation has eliminated speculation. The volume of business ahead promises to be normal, according to leaders in the commercial world to-day.

The results of the coming crops, of transportation remedies, and regulation of the manufacture of non-essentials were the only uncertain factors in the situation. The wheat and corn belts in 1917 enjoyed the greatest prosperity in years. Increased acreage of winter wheat, rye and oats foreshadow a promising output, encouraged by recent snows in Oklahoma and Kansas which saved much planting.

### SUBSTITUTE FOR PAPER

A NEW product for making paper has been found in zacaton grass, known also as broom-root grass and wire grass, from the fact that the roots are extensively used in the making of brooms and brushes. The tops, though, have hitherto gone to waste. Now it is discovered that these neglected tops make a fine grade of paper.

Zacaton grass extends from California and Texas southward to the Argentine Andes. It grows most profusely, however, in the mountain regions east and west of the city of Mexico, where it is harvested for the sake of its roots.

An acre of grass should yield at least three tons of tops. The plant is a perennial one, the growth being almost entirely from self-sown seed. Unless checked by fire, cultivation, or the harvesting of roots the grass will soon cover a field solidly, and it is not uncommon to find many square miles densely covered with the growth. The range can be profitably gone over for roots every third year.

Laboratory tests of this grass conducted by the United States Department of Agriculture show that it can be chemically reduced to paper stock by the soda process more easily and with less expense than is necessary to reduce poplar wood. The same processes and methods which are employed for the manufacture of pulp from poplar wood are quite suitable for the treatment of zacaton, but in place of the wood sawing, chipping, and screening machinery a grass duster is necessary.

The paper manufactured from the stock has proved as satisfactory in physical tests as a first-grade machine-finished printing paper. It has, moreover, a very satisfactory appearance and feeling.

### B.C. FUR TRADE PROSPEROUS

APPROXIMATELY two million dollars were realized by British Columbia trappers last season, according to figures tabulated by Provincial Game Warden Bryan Williams, who based his calculations on the returns made by the 947 of the 1,161 licensed trappers who have filled out and returned the forms demanded by law. These show a total fur value of $300,000, to which must be added $100,000 worth of coyote pelts, which come in under a separate heading in the classification. All licensed trappers are whites, but as there are at least six unlicensed Indian line runners for every white man, Mr. Williams is confident that his estimate of $2,000,000 is well within the mark.

During the season in British Columbia from November 1 to April 30 many trappers make over $2,000, and in rare instances is the fur harvest less than $1,000 for the six months' work. In 1917 the prices paid by local agents have been unusually high.

### NICKEL SILVER

THE war has killed the popular name of one of our most useful alloys—German silver. Even before the war the Alloys Nomenclature Committee of Britain had suggested its alteration, since the alloy was neither "German" nor "silver." As a matter of fact, the alloy was introduced from China, and is composed of copper, nickel, zinc. The higher the proportion of nickel (which ranges from 30 per cent. down to 7 per cent), the better the quality of the alloy. The copper is always over 50 per cent., and the zinc varies from 20 per cent. in the best mixtures, to 35 per cent., in "fourth." The alloy is thus really a nickel-brass, and may be so described with precision, but the name is hardly so attractive as nickel-silver, which is the one that will in all probability, except for scientific purposes take the name with the German sound. Nickel-silver in some text books is given the name of "pack-fong." Assuming this to be derived from Chinese, it is incorrect and should be "pack-tong" "pack" meaning white, and "tong" being the Chinese for copper.

### 1917 TOTAL TRADE REACHES MAXIMUM

INTERNATIONAL trade of 1917 will show a larger total than in any earlier year. This estimate, appearing in "The Americas," issued by the National Bank of New York, is the result of a careful review of all available figures of world trade for the year 1917. It includes eleven months' actual figures for the United States and United Kingdom, ten months for Canada, and somewhat shorter periods for the year to justify an estimate that the total international trade of the year will be the largest in history. In the case of the United States the total trade of the year is estimated at approximately nine billion dollars, against less than four billions in 1913. In Great Britain the total for the eleven months is over seven billion dollars, against five and three-quarter billion dollars in 1913.

Canada's total for ten months ending with October is over two billion dollars, against $88,000,000 in the same months of 1913, and Japan for the nine months ending with September, $914,000,000, against $507,000,000 in the corresponding months of 1913. For France no official figures are available for 1917, though the imports estimated by an examination of figures of export from other countries to France are apparently about 50 per cent. more than in 1913.

In the Central Powers no official figures are available, though it is known that their over-sea trade is, of course, cut off; they have imported very largely from adjacent neutral countries, and the exchanges between the countries forming the group now known as the "Central Powers" have also been very great. In the Allied countries a part of their trade, that conducted by or on behalf of the Government, has been omitted from the official figures.

#### Allied Figures

The largest change is that of the Allies. The total trade of Great Britain, France, Italy, Russia, United States, Canada and Japan in 1913 was a little more than eighteen billion dollars, while the figures thus far reported for the current year suggest that their total for 1917 may approximate twenty-five billion dollars.

Oriental trade of 1917 will somewhat exceed that of 1913. In Japan exports are double those of 1913, and imports show an increase of about 50 per cent. In China the imports show a decline, and while there is a good demand for her silks at high prices, the best markets for her tea have been difficult of access. India shows a decline in imports and a slight reduction of exports, due chiefly to lack of transportation. The great rubber plantations of Ceylon, the Malayan Peninsula and the Dutch East Indies, however, show large increases in their production and sales, and the sugar output of Java was larger and at higher prices than formerly.

The neutral countries of Europe show material increases in the value of their exports, but slight decreases in the value of their imports.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

## DANGER-SIGNS

By [illegible]

DANGER SIGNS are silent sentinels which serve to warn workmen of a possible danger within the surroundings where these are placed. They may be considered as a temporary adaptation to prevent accidents, or for use in an emergency, while other means are being devised for safety purposes.

They should never be used as a permanent means for preventing accidents.

DANGER SIGN HOLDER AND SUGGESTED NOTICES FOR USE ON SAME

For in most cases where a danger-sign has been installed, a safeguard or some acident protective device is required.

In accident-prevention work, little thought has been given to a method for making danger-signs of standard dimensions nor for having them properly worded or of sufficient attractiveness to command one's attention. Except those issued by insurance and other accident liability companies, most danger-signs are but makeshift affairs at best.

Warning notices that are unintelligibly scrawled on boards or paper if not readable by all who approach them are of little worth as such. Then again, if a danger-notice has become torn or soiled, or even removed from position, while no one is responsible for its care or replacement, it follows that accidents are liable to happen.

The work of preparing danger-signs is a part of safety-engineering, equally important with devising safeguards. They should be of elaborate design, of neat appearance and properly placed so that workmen will in all circumstances heed their warning. The same degree of interest, care and attention should be given their design and arrangement as is expected of the workmen in observing precautions for avoiding bodily injuries. If a sign is carelessly made up, and indicates indifference in its preparation, [illegible] will show a similar carelessness and indifference to the sign or the place where [illegible]

The accompanying sketch shows a few [illegible] size and also a design of a sign-holder. Danger-signs, as a rule, are usually tacked up on walls or boards. When so placed, they do not always indicate where the danger lurks. The word "Danger" painted on a sign denotes no particular point or place where attention is required, and are almost valueless because of this omission.

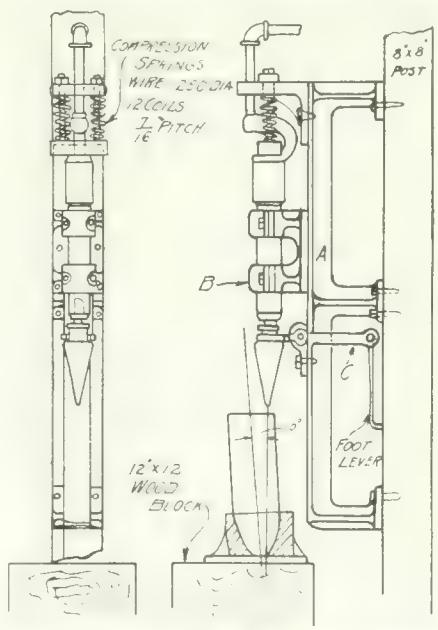
At the top of the rod of the holder is an arrow, that can be adjusted so as to point near, or directly to, the danger exposed. The holder, as seen, consists of an iron base having an upright rod to which is attached a sign-holder at the upper end. The base and holder rods are slit on the points for inserting the sign and arrow. These are held with pins or rivets.

The arrow strip should be about 12 or 14 inches long and of red color. The holder when placed about in zones of danger containing the arrow and sign will be found more serviceable than any devise now in use. Their novelty and attractiveness cannot fail to compel attention from the most indifferent workmen.

## HOW TO ADAPT AN AIR HAMMER TO SHELL WORK

By G. Barrett

A SIMPLE and convenient arrangement for supporting and working any make of air riveting hammer, for use on base



METHOD OF ADAPTING AN AIR HAMMER TO SHELL WORK

plates of 6-in. shells is shown in the accompanying sketch. I have designed this hammer in order to eliminate the necessity for holding the hammer by hand, which is a cumbersome method and hard on the operator.

The hammer is mounted on a bracket casting which allows it to be attached to a post. The barrel of the hammer is allowed to slide in bearings of bracket B, so that by putting pressure on the foot lever, the operator lifts up the hammer and puts the shell in the position shown in the sketch. The springs C are to keep the tension on the hammer while the piston is striking the blows, and all the operator has to do is to revolve the shell by hand.

## LAZINESS INDUCES EFFICIENCY

By D. Middleton

WILSON was a big overgrown youth who held his job because he was a pal of the boss's son. Wilson was lazy. The foreman tried to give the men the kind of work they liked as far as possible and in Wilson's case a job of countersinking the little butt shown was "it." The work was merely taking off the sharp corner and was done on a sensitive drill holding the pieces with a pair of pliers. Pretty soft for a big man but it suited Wilson until the day when the foreman was away when the exertion of reaching for the hand feed lever became too great. So all by himself he hunted up a piece of twine, tied it around the pinion shaft, and carried the ends down to the floor where they were made into a kind of stirrup for the size nine foot of the operator. But the point is that it worked and with his arms resting on the table, he had only to move his wrists to pick up a butt and it in the pliers; a back and forth movement of the foot brought the countersink to the work very neatly and the production was just about doubled.

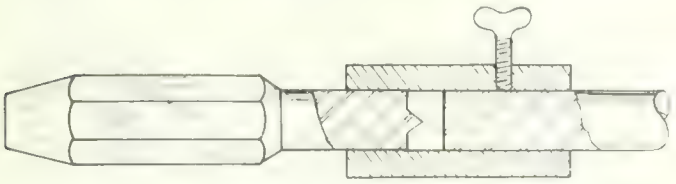
## MACHINE SHOP HINTS FOR BENCH HANDS

By J. Davies.

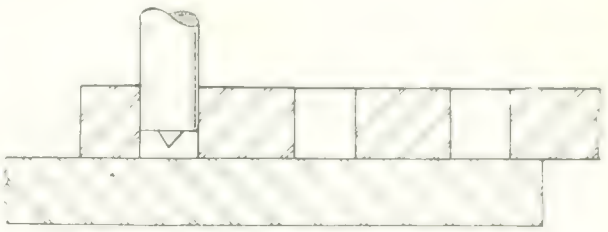
WHEN there is no centring machine or device for automatically finding the centre of shafts, etc., which is often the case, the following little tool will be found very useful, particularly on repetion jobs. Supposing there is a large number of pieces to be centred all the same size, first bore out a small piece of machinery steel to size of pieces to be centred; then turn up a centre punch to fit the bored hole, and put the bored piece on the shaft which is to be centred, leaving a portion sticking past the end to act as a guide for the centre punch (see Fig. 1, which indicates clearly the method of using). By having different sized bushes the outfit can be used for several sizes. In marking holes in boiler plates this rig is very handy owing to the impossibility of using centring devices even when available.

### Reducing the Bore of a Bush

If in finishing a hardened steel bush it should happen to be ground out a few thousandths too large, the size of the hole can be reduced enough to allow for regrinding by heating slowly to a nice cherry red, then placing a piece of asbestos over each end large enough to cover the hole; hold the asbestos tightly against the hole with a pair of tongs to prevent the water from getting into the hole and cool off.



SIMPLE ARRANGEMENT OF CENTERING TOOL FOR USE ON REPETITION WORK.



ROLLER PLATE ADJ

If cutting off flat stock, say, ½ in. x 2 in., with a power hack saw, place it edgeways in the vise and it will be cut through in half the time it would take to cut it flatwise. In cutting slots with a hand hack saw it is sometimes very convenient to place two blades in the frame to cut a slot the required width.

### Chipping Key Seats by Hand

In cutting a key seat by hand it is of prime importance to have it clearly and accurately marked out; after marking off with a box square or key seat rule, the sides should be marked out with a side-cutting chisel or an ordinary chisel ground quite thin and held at such an angle as to bring its cutting edge in line with the side of the intended key seat. This cut or deep mark will prevent the material from tearing out along the sides of the keyway while making the first cut with the chisel. If the key seat is a narrow one it may be cut with a chisel the required width. If the key seat is a wide one, take a narrow cut down each side with a cape chisel, then chip out the remaining metal from the centre. In some cases it is easier to drill a series of flat-bottomed holes along the length of the key seat, then remove the remaining metal by hand; of course, this only applies when no better conveniences are at hand.

In taking a cut off a very large surface by hand, first mark it off with a surface gauge all round the outside edge, then take a chamfering cut down to the depth; this will help the chisel to take a grip of the metal in starting the cut, and also prevent the metal from breaking away at the finish of the cut. Take a series of cuts across with a cape chisel, leaving the metal between the cuts a little narrower than an ordinary flat chisel; this materially lessens the work of the flat chisel, as the metal breaks away readily when it has no supporting edges. Don't use a hammer for steady chipping that is too heavy; use one you can swing easily from the end of the shaft, and don't have to get a strangle hold on it; it isn't the man with the biggest hammer that does the most work.

### Filing

Filing is at once the commonest and yet the most difficult art of the machine shop; the novice is at once proclaimed by the first few strokes of the file. Volumes have been written about it, yet it is as useless to expect to become proficient in the use of it by simply reading an article in a technical paper as it is to expect to become a good violinist by taking a correspondence course. The man that can wield the file well is just as much of an artist as the man that wields the violin bow, and for that reason I shall not attempt to give any detailed instruction, but merely point out a few facts.

When a novice is seen laboriously using a file he is often told as a joke to put some oil on it. In some cases this is actually beneficial. On cast iron or broad smooth surfaces oil should never be used, although it may be used to advantage when filing wrought iron if the surface is not too broad, as oil prevents the file from scratching and cutting too deep.

Chalk rubbed over the file tends to prevent the teeth from becoming choked up with filings or cats' paws, as they are often called. A new file should not be used on rough cast iron surfaces from which the sand and scale have not been removed.

To the uninitiated it would [illegible] a file with a perfectly flat surface would be preferable; this is not so, it would be extremely difficult to file perfectly flat with a flat file. The face of a file is made convex for three reasons: (1) To overcome the spring due to the pressure of the hands; (2) to prevent them changing their shape sufficiently during hardening to make them concave; (3) so that the file will not bear all over a wide surface, as it would then require a heavy pressure to make it cut.

To put a handle on a file, put the file in the vise with the tang protruding past the end of the vise, give the end of handle a slight blow with the hammer, then turn the handle round, continue the operation until you judge you can drive the handle well on to the tang without splitting it.

Frequently in counting the number of teeth in a gear wheel, after counting round the wheel you forget whether you counted the one you started with or not. Avoid this by always marking the gear opposite a space and then counting round.

Putting very small screws into an awkward place may be much simplified by having the end of the screwdriver loaded or magnetized. The screws will then adhere to the end of the screwdriver while being placed in position. Wood screws can be screwed home easier if they are smeared in heavy oil or tallow, and may be successfully screwed into the very hardest wood by the following method: Drill a hole equal in diameter to the size of the screw at the bottom of the thread, and take a screw the size to be used, file it to the form of a half-round bit, when it practically becomes a tap; screw this into the hole and it will form a thread which the screw to be used will readily follow.

## GRINDING THIN HIGH SPEED STEEL KNIVES

By Philip H. Clapp and George A. Parks*

THIN high speed steel knives range from ⅛ in. to ¼ in. in thickness, 1 in. to 2 in. in width and from 1 in. to 42 in. in length. Owing to their composition and the treatment given during manufacture, knives of this type are extremely hard and brittle. The only efficient method, therefore, of sharpening is by grinding.

#### The Grinding Wheel

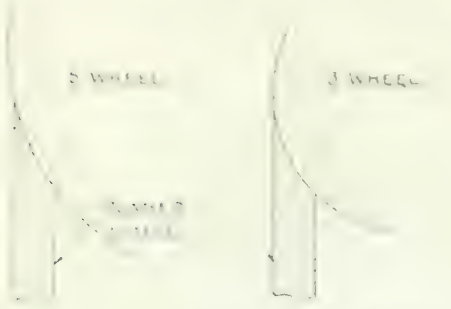
One of the most important factors in keeping the edges of high speed steel knives in good condition and in preserving the life of the knives is the selection of grinding wheels of the correct grain and grade. Many of the common troubles such as cracking and checking of the edges may be avoided if the right wheel is properly used.

The grinding wheel should be of a grain and grade which will cut freely and rapidly with very little dressing and yet maintain its shape. The speed should not exceed 5,000 s.f.p.m. A wheel operated at too high a speed acts hard and devolops the tendency toward glazing and dulling over.

On the modern knife grinding machines 2,630 or 2,636 grades J or K Alundum vitrified wheels will be found almost universally satisfactory. Very little dressing is required, and a cool, rapid cutting action is given, with a reasonable feed and traverse. Occasion-

soft as grade I or even H, but this is unusual.

slower wheel speeds and in most cases smaller wheels were used. 2646 J or K are sucessful. Here, too, softer wheels must sometimes be used, especially if



SHOWING DIFFERENCE IN BEVELS OF KNIVES GROUND ON IN AND IN DIA WHEELS

the knives are particularly hard or the contact between the knife and the wheel is exceptionally broad because of a long bevel.

Moulding knives and others of special design which are usually milled to original shape, are ground by hand to the required bevel on an ordinary bench grinding machine. For wheels ½ in. and thicker, 2636-M Alundum vitrified has been found successful. For wheels thinner than ½ in., 2646-M Alundum vitrified is most suitable. These moulding knives are afterwards jointed to the exact contour required, by means of a master form which controls the movement of the jointing stone.

### Methods of Grinding

Usually the planing machines are so constructed as to permit of the ready removal of the knives for grinding. Gradually the old type of knife grinding machines which required the constant attention of the operator is being replaced by the modern automatic machines. The traverse of the work carriage and the feed of the grinding wheel are both automatically controlled. By means of stops properly arranged the movement of the work carriage can be regulated to conform to the length of the knife or knives being ground. Several short knkives can be ground at a time, and this practice is usually followed as the knives are then almost certain to balance one another in weight.

The question of a properly balanced cylinder naturally depends mainly on the weight of the knives although their mounting in the cylinder should also be carefully watched.

In a majority of shops the grinding is done against the edge of the knife, the direction of the wheel being from the edge toward the back. This method reduces the burr or feather edge, which is always present along the knife edge after grinding; when grinding toward the edge from the back of the knife, this feather edge is much more pronounced and requires more honing with a fine abrasive stick or oil-stone before ready for use. The degree of sharpness produced by either method does not vary greatly.

Although the grinding in most of the present day shops is being done dry, it is by no means an established fact that this method is superior to the wet method. With a copious supply of clean lubricant which also serves as a cooling agent, the knives can be sharpened fully as satisfactorily as when grinding dry. The principal objection to the wet grinding method as tried in some of the shops, is the extremely small amount of lubricant applied to the point of contact between the knife and the wheel during the operation. An insufficient supply of lubricant is far worse than none at all. It is not enough to keep the edge cool while the grinding is being carried on, but rather tends to chill it suddenly after the wheel has passed. Therefore, the expansion caused by the heat generated while grinding is suddenly reduced and this abrupt reaction in itself is quite enough to cause checking of the knife edge.

The feed of the grinding wheel can be set for any desired limit and when a corresponding amount of material has been removed from the knife, the wheel feed automatically stops. A small allowance must be made for wheel wear if the knives are long and much stock is to be removed.

When grinding knives, light cuts should be taken so that the heat generated will be reduced to a minimum. The actual depth of the cut to be used with best results, depends on the type, thickness and kind of knife as well as on the bevel to be ground. A fairly slow carriage traverse, not over 15 feet per minute is also recommended so as to enable the wheel to remove the stock without being forced.

These facts are especially true when grinding a double bevelled knife as the wheels are cutting at almost the same place on the knife edge, thus causing noticeably more heat than when only a single or clearance bevel is being ground. No doubt they are working under severe conditions when in operation and this "rest" tends to relieve some of the internal strains which may have been set up while in use. Still others are of the opinion that this "rest" should take place after the grinding and before the knives are again mounted for use.

If the grinding is being properly performed and the wheel is of the correct hardness and fineness, there should be practically no additional stress set up by the grinding operation. It would see, therefore, that the greatest advantage would be derived by letting the knives "rest" before grinding and paying particular attention to the selection of the proper grinding wheel.

### Keeping Wheel in Condition

The usual method of dressing the grinding wheel is by means of a Crystolon stick about 16 grade S vitrified. The wheel face is touched lightly from time to time, the frequency depending upon the action of the wheel in use. The grinding wheel face is thus sharpened, or in other words the dull grains are removed and new sharp abrasive particles are presented which in turn give more satisfactory results. It is possible also for a skilful operator to restore the shape of the wheel face with one of these Crystolon sticks.

One of the greatest objections to some of the old types of knife grinding machines was the use of a wheel with too small a diameter. Each shop or mill usually has a certain standard length of bevel, depending upon the wood to be cut, which is measured by a gauge, and the knives must be ground accordingly. When the grinding wheel had worn an inch or more in size, the bevel produced on the knives naturally became so concaved as to weaken the cutting edge considerably. This is illustrated in figure 1 showing the bevels ground by a 5 in. and 3 in. wheel respectively. This condition is being eliminated in the modern machines through the use of larger wheels.

### Causes of Cracking, Checking, Etc.

It is needless to say that upon the grinding depends largely the efficiency of the knife. Complaints have been made to knife manufacturers, alleging that their knives crack and break. Investigations in some cases have revealed that the fault is not in the knife itself, but rather in improper or abusive grinding. Improper grinding will injure the best high speed steel knife ever made.

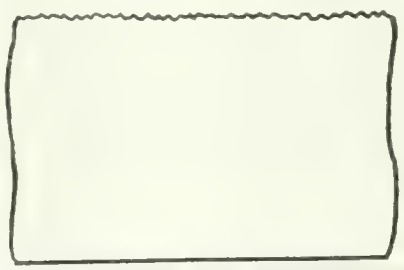


FIG. 2. MAGNIFIED EDGE OF SOUND KNIFE WHICH HAS BEEN CAREFULLY GROUND.

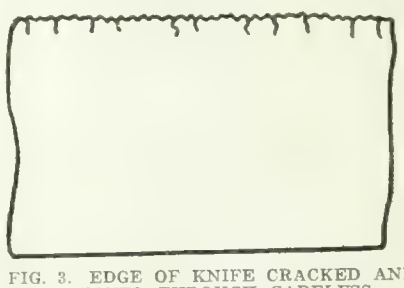

FIG. 3. EDGE OF KNIFE CRACKED AND CHECKED THROUGH CARELESS GRINDING.

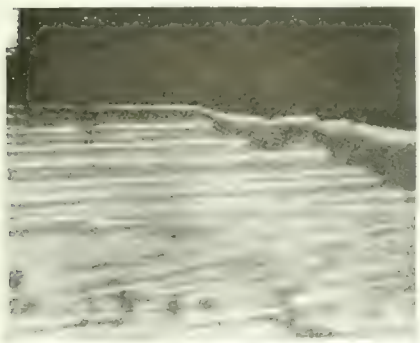
There are several causes which contribute toward shortening the life of a high speed steel knife by making frequent truing and grinding necessary. Vibration, especially that which may be caused by excessive cylinder speeds, light foundation or machine construction, loose boxes or any other poor conditions is to be avoided in so far as possible. The service given by the knives between grindings is not only materially shortened by this factor but

the cutting efficiency of the machine is seriously decreased.

Under the impression that time is money, some operators hurry the grinding by taking excessively heavy cuts. This is absolutely wrong and should not be allowed under any condition. The edge of the knife is burned and checked, and naturally when it is placed in



DULLED EDGE OF A PLANER KNIFE

Magnified 50 diameters

Magnified 50 diameters

[illegible] OF KNIFE GROUND [illegible]

[illegible] 50 diameters

operation, pieces break out or the edge may even break down altogether, depending upon the extent to which it has been injured. This practice of taking too deep a cut is being automatically discouraged through the use of very light belts on the modern grinding machines. This will cause the wheel to stall, rather than cut under the excessive pressure.

Then again, checking is frequently produced by too hard or too fine wheels which glaze over on the cutting face after being used for a short time. A glazed wheel is not a cool cutting wheel because the cutting points are dulled over and naturally greater friction occurs between the work and [illegible] than is the case where a clean, sharp wheel face is maintained. Obviously, more heat is generated.

The edge of a knife, greatly magnified, resembles figure 2. The heat generated during abusive grinding is usually sufficient to cause cracking or checking as shown in figure 3.

The cracks are caused by the rapid expansion of the steel due directly to the excesive heat concentrated on the knife edge. This unequal expansion, due to the heating which is applied only to a small portion of the edge at a time, causes internal strains in the knife which are oftentimes severe enough to cause checking.

Although the cracks may not be of sufficient size to cause breakage after the first grinding they are aggravated by each subsequent grinding until the edge of the knife is so weakened that the first knot in the lumber breaks out a piece. Even if checking does not actually occur during the improper grinding, the resultant stress existing in the steel will sometimes find relief through this channel, while the knife is being used.

Sometimes, too, pieces will break out from the edge during grinding because some machines are equipped with a device for truing the knives while they are in motion so that they will revolve in a true circle. This equipment is nothing more nor less than a means of holding an abrasive stick rigidly, and moving it along parallel with the edges of the knives. The abrasive stick reduces any of the protruding knife edges until all of them are operating in a true circle. The cylinder is then ready for use in planing lumber and each knife will perform an equal share of the work. The jointing must be done at the same speed as the cylinder is to be operated when in use, as the paths of the knives depend directly on the peripheral speed.

The most satisfactory results in jointing have been obtained by using machines especially built for this work. For special shapes such as moulding knives, master forms of exactly the same shape as the finished knives may be inserted to guide the jointing stone back and forth across the edges of the knives [illegible] of an improper contour.

A series of knives may be jointed a number of times before it becomes the wood and the efficiency of the knife from that point until the bevel is reground decreases rapidly. This particular feature is closely watched in most of the woodworking shops, because the speed of cutting is reduced rapidly and the additional strain on the knives and machine is to be avoided.

For jointing, some operators prefer to use a wide stone while others select a narrow stone and hardly any two types of machines seem to agree on the shape. It is essential, however, that the jointing stone be narrow at the point of contact with the knife edge and that light cuts be taken so as to avoid burning.

For the [illegible] or N Crystolon vitrified has proven most satisfactory. Occasionally, an operator prefers a [illegible]

### Jointing

Because there is some distortion of the cylinder and knives when working under actual operating conditions and because the knives cannot be ground and re-set perfectly in the cylinder, of the incorrect conditions under which the operation is being carried on.

necessary to remove them from the machines for regrinding. The width of the heel, caused by the jointing, which can be reached before grinding is necessary, must not greatly exceed 1-32 in. However, this depends somewhat on the kind of material being cut.

When the heel produced by jointing becomes too wide, the rear edge strikes

and on his personal opinion.

### GERMAN ECONOMY IN LUBRICATING OIL

Notices are displayed in German machine shops, giving hints on economy in lubricants which should be valuable in any country. These are:—

Use only closed oil cans, with spouts that will deliver drops, or at most only a thin stream.

Use all lubricating apparatus strictly according to the instructions, and put the oil only where it will actually lubricate. If a machine has automatic droppers, shut off the supply while machine is standing.

Do not use cylinder oil on shafting or elsewhere when cheaper oil will answer.

Keep all rubbing surfaces in good condition. Rough surfaces and too-tight boxes consume more oil. Worn and leaky bearing waste oil.

Always use drip pans and arrange to filter and cleanse the oil so caught. It is as good as new.

Collect all greasy waste and wiping cloths, so that the oil may be recovered. Never burn them.

Be careful about using lubricating oil for cooling a bearing. Water will often do as well.

[illegible] ing and polishing. Never clean the hands with oil. A greasy cloth will do as well.

Toronto Harbor Development [illegible] not proposed to stop work on the Toronto Harbor improvements, certain necessary work will be continued. The eastern ship channel is to be gone on with and completed, as well as the 900-foot dock extending out from the marginal way. The sea wall in Ashbridge's [illegible] is all in the east end. In the west end a section of the uncompleted breakwater [illegible] be completed.

### SHOP GEOGRAPHY

THE instruction of the men in a factory seldom goes beyond that of the actual work upon which they are engaged. The advantages that are to be derived from the workman becoming more familiar with the plant layout are worthy of more consideration on the part of shop officials than might be generally supposed. One very important factor in connection with shop geography is the advisability of identifying the numerous piping installations that are now so common in the average manufacturing establishments. In addition to classifying different lines of piping by means of some color arrangement, charts should be made and placed in conspicuous locations about the shop, so as the employees may be able to act in case of emergency to avoid loss or destruction of life and material.

A few years ago while the writer was working in a large sheet metal plant an experience met with emphasized the extreme advantages that would result from the workmen having a better knowledge of shop conditions and current developments. For several weeks prior to the time in question, pipe fitters had been engaged in installing a new sprinkler system throughout the various departments. The climax came one night when four or five tool makers were working overtime. The day before the water had been turned on in the system to test the piping, and apparently everything was satisfactory. This night, however, while one of the men happened to be in a comparatively isolated portion of the factory, he noticed water dripping from the ceiling above; upon advising the foreman the latter investigated and going to the floor above found a large area of the floor already covered with water, which was now flowing freely in many places from the second storey ceiling. Continuing up to the third floor he discovered a section virtually flooded to a depth of three or four inches and a stream of water running from a large drying kiln. The foreman immediately endeavored to stop the flow from the released sprinkler but the force of the vortex prevented him from stopping the opening.

It is just here where the absence of shop geography resulted in considerable damage to much of the finished tinware and wire articles that covered the floors in the vicinity of the "blow out." The few men then on the premises did not know where to shut off the source of this water supply, and telephone communication was necessary to bring the superintendent to the scene before the yard valve could be closed; while during the interval the several tool makers were baling water from the floor and pouring the same into nearby sinks. The cause of the "break" was the placing of a "185 degree" sprinkler in a kiln that very often was raised to a temperature of nearly 200 degrees. If the men working at the time had known the locations of the different valves, much time and loss would have been avoided.

### WANTED—INITIATIVE ABILITY

By R. Hamilton

INTELLIGENT application of the elementary principles of mathematics and mechanics is not only a factor in the education of the engineering apprentice, but a conscientious study of the theoretical part of his work is essential to the attainment of an end that every young man should strive for. As the "boy is father to the man" so also is the apprentice father to the engineer. No other trade or profession is more exacting than that of the mechanical engineer; the rapid strides and remarkable achievements of science and industry during the past decade has only been possible through the concentrated efforts of those men responsible for its accomplishment. It is true that the dominating feature that characterizes the production of materials at the present time—particularly in metal working establishments—is largely a physical one, but it is equally true that without the modern equipment now in use the efforts of the man would be more or less fruitless.

Developments of machinery, both in the way of improvement and invention, have enabled manufacturing to progress with almost miraculous rapidity, as has been amply demonstrated during the past three years. Present methods of shell production have not been the result of any one man's efforts, or even of any particular class of men, but are rather the evolution of numerous ideas, many of which had their origin in the ordinary practice of pre-war activity. This evolution, and in some respects revolution, of production methods is really due to those men who were mentally responsible for the initial development of those devices, special attachments, and single purpose machines, which have been largely instrumental in the success of the industry.

The efficiency of a plant and the quality of its product are practically dependent upon the efficiency of the individual. The executive possibilities of the organization may count for naught unless the full co-operation of the workmen is given to the solution of the problems that are part of the routine work of every establishment. Every workman, even though in the most humble position, should not only realize his own personal responsibilities, but should seize the opportunities that are constantly open to him to advance his own interests. Trivial and apparently insignificant details should form the basis of developing the initiative of an employee; not only should these details be regularly and conscientiously performed, but they should be studied with the purpose of improving the manner in which they are accomplished, eliminating wherever possible any unnecessary waste of effort. Some may imagine that "it is theirs to do and not to think," this latter being the duty of the man higher up, and while invariably this is the case it is quite obvious that the "boss" did not attain his prominence through the too prevalent spirit of human indifference.

Through the force of circumstances the young man of to-morrow will be compelled to take larger responsibilities than ever before and it will be necessary, therefore, that they should so school themselves that the future will not find them lacking in a sphere where originality, initiative and a thorough knowledge of elementary principles are the fundamental and dominating factors.

### THE DANGER IN FLYWHEEL AND PULLEY WORK.

By D. A. Hampson

MOST of us look upon the beautiful curved arms to be seen in the large pulleys of thirty years ago as the work of designers who were architects rather than engineers and a relic of the days when time was not at a premium and iron was cheap. In reality those curved arms served a purpose and did it well. The foundry art had not reached its present high state of development and the curved arms were a protection against contraction strains, and against the cracks that we find, even to-day, where the arm joins the rim. The curve being elastic to a certain extent, was not as rigid as is the straight arm of to-day, and if the arm cooled last, its shape allowed it to give and not break. If the rim was extra heavy and the arm cooled first, the contraction due to the drawing away from the rim simply straightened out a little of the curve and all was safe.

But even with our present experience, the thin rim and the straight arm of to-day continue to give trouble in the shop if a sound casting is not properly handled. Flywheels, with their heavy rim mass and relatively light arms, are hard to cast and easily broken in the shop processes. The trouble occurs where the arms and rim join. If an arbor is forced in or out of the hole or a key driven home or any driving in the direction of the axis, there should be sufficient resis-

tance applied to the hub to take all of the thrust and also the rim supported so it cannot vibrate. To press in an arbor with the pulley resting on the rim and the hub free is only to court breakage. To drive on an arm or the rim is as bad. The iron is already under a strain and the shock of the blow causes even greater strains to be set up and fracture occurs.

The writer saw a key and shaft being fitted to the flywheel of an air compressor. The wheel weighed about a thousand pounds and was stood upright on the floor with a chain hoist to steady the top so it couldn't fall over. The shaft and the key were made a driving fit—both driven home with a 16 lb. sledge and it would have been a dandy job if the hub had been rigidly supported against the blows and the rim had had a positive means of steadying, which the chain did not give. The machine was assembled and started up but no sooner had it reached speed than with a loud report, two of the arms snapped. The wheel had been perfectly sound when machined and while it may have been jarred in handling, the true solution is that the hammering it got in the shop was the cause of breakage.

## USES OF COAL-TAR PRODUCTS

By O.C.

WOOD, when exposed to moisture or set in water, may decay through the action of different organisms or fungi, or it may be destroyed by insects. To prevent this the timber is soaked in some chemical which will act as a poison to such enemies. Mercuric chloride, copper sulphate, and zinc chloride are examples of suitable poisons, and of these the last named is widely used. They are, however, all soluble in water, and may be rather quickly washed out by rain, etc. Creasote oil, on the other hand, is an efficient preservative which is insoluble in water, and consequently is more permanent in its action. It gradually evaporates, but if a heavy oil be chosen, the rate of evaporation is very slow. Creosote oil is the most suitable material for timber preservation, and is most used in Canada. Coal tar, also insoluble in water, is often used, but its penetrating power is very small.

The wood to be preserved by creosote is put in iron tanks, which are then closed and evacuated; the heated oil is now run in and the wood allowed to remain immersed under pressure for some time to ensure the complete filling of the pores. The preservative, to be effective, should contain high-boiling oils; for general purposes not more than 50 per cent. of it should distil below more than 315c. But for wood paving blocks not more than 55 per cent. should distil below that temperature. Economy of creosote oil can be obtained by the use of an inferior oil, which would be mixed hot, in the proportion of 80 parts oil to 20 parts of coke-oven tar, the latter containing not more than 5 per cent. to 6 per cent. of free carbon. The penetration of such a mixture is not less than [illegible] of the creosote oil, if the time for which the timber is kept under pressure be slightly increased.

### Annual Oil Consumption

On the American continent the demand for creosote oil is much greater than the supply. In 1913 the United States consumed, for timber preservation, over 90 million gallons (Imperial) of the oil, and of this 62 per cent. was imported from Europe. Between 60 per cent. and 70 per cent. of the total quantity of oil consumed was used for the treatment of railway ties, some 25 million being thus treated. In Canada, 19 million cross ties are used annually, and only about 10 per cent. of these are creosoted; but even for this comparatively small number Canada does not produce sufficient creosote oil. If all the tar produced in gas and coke-oven works in Great Britain were distilled, the home supply of creosote oil would still be quite unequal to the demand, and tar distillers would therefore be certain of a sale for one of their most important products.

Raw tar is sometimes used in the making of roads, but it is better to employ the prepared or dehydrated tar. This is generally poured or sprayed on existing roads. In dry weather it serves to keep the surface free from dust, and in wet weather it protects the road material from the distinegrating effects of water. In the actual construction of roads, coal-tar pitch and asphalt are much used instead of tar. Coal-tar asphalt is made by mixing pitch with suitable quantities of creosote and anthracene oils; and although it cannot entirely replace the natural asphalt [illegible] very good substitute. For making sidewalk, a mixture of coal-tar [illegible] natural asphalt is often employed, sandy material being ground up with the mixture, which is then melted and mixed with gravel. The use of pitch, etc., in the making of roads is increasing rapidly, and even at the present time there is a good demand for this residual material from the distillation of coal-tar.

### Other Products

Carbolic acid, another coal-tar product, in its pure crystallised state, is used for medicinal purposes as an antiseptic, etc., but it has a much wider application in the crude state for disinfectant purposes generally. The impure carbolic acid has a strong unpleasant smell. It becomes partially liquid on standing, and in this state is much used for disinfecting sewers, stables, etc. Various preparations [illegible] made to render the application of the disinfectant more convenient. The most important preparations are those in which the phenols are combined with soap; but carbolic-acid powders, which are mixtures of carbolic acid and lime, etc., are extensively used. Naphthalene sometimes replaces carbolic acid, as a disinfectant, being used in sick rooms, etc., and is often preferable to carbolic acid for the dressing of wounds. It also acts as a preventive against all kinds of moths, etc.

## VARIABLE SPEED TRANSMISSION DEVICES

IT is curious to note how after a century or more of intense mechanical development some of our most widely used machines and mechanical devices are of a type that appears to outrage every mechanical principle. The picking motion of the loom is one such device, the combination of motor cycles and side car is another, the sliding gear variable speed device for power driving road vehicles and other machines is a third. A study of some of these apparently barbaric suvivals leads to the conclusion that their practical advantages outweigh fundamentally their technical deficiences, and suggests that they are not likely to be superseded by more "correct" devices that will better satisfy the mechanical sense. They may be all wrong, but they give more for a dollar than any alternative arrangement. But in other cases they appear to owe their continued existence to the fact that being early established as a standard device, a hundred times more effort has been given to their improvements than to the development of any radically different and, perhaps better method, so that the competition continues to be between an actual much improved bad thing and a prospective ill-developed good thing.

Whether the sliding change speed gear now employed on the overwhelming majority of road motors belongs to the first or second of these arrangement classes it is as yet too early to say, but the arrangement is too crude to go for a long time unchallenged. R. E. Phillips in a paper on variable speed gears, read some time ago before the Institute of Mechanical Engineers, admits that although from an engineer's point of view it is theoretically an embodiment of everything that is wrong, it has been developed by the perfection to which its design has been brought, by the high standard of workmanship employed in its manufacture and by the use of the highest grade of materials into a completely satisfactory piece of mechanism. In practice it has proved to be "not so bad as it looks," and it has managed to hold its own for nearly 20 years against many other gears which theoretically should give better results. This condition of things has attributed, however, partly to the factor above mentioned, that nothing like the same attention has been devoted to other transmission devices as to this, and partly to the fact that the motors now used are of such a high horse power that at least 75 per cent. of the running is now done on the direct drive.

The amount of effort that has been given to the improvement of the side meshing type of change-speed gear is [illegible] been catalogued by M. Rutishauser, an eminent French engineer, into no fewer than 9 main divisions and 20 sub-divisions. The most frequent aim of the inventor has been to prevent undue wear

and tear on the teeth of the wheels due to the clash engagement, and the problem has been tackled in many ways. The side mesher action can, of course, be altogether at a price. All that is necessary is to keep the several trains of gears constantly in mesh, and bring into action the particular train required by means of some of some form of clutch. This method, though theoretically attractive, has in practice three weighty drawbacks; it increases the length and weight of the gear box; it adds greatly to the complexity and cost and it means that all the wheels are running all the time. A happy compromise is that in which the sliding wheels are mounted loosely on their shafts, and are brought into mesh with the respective corresponding wheels of their trains before they became coupled to the shaft on which they are mounted.

## EXTREME DUTY OF AEROPLANE PROPELLERS

TO be trustworthy an aeroplane propeller must be one of the strongest things in the world. Not only are they subjected to gunfire, but their normal action makes heavy demands on their strength. The very speed of their revolutions tends to disrupt them. In a test run of propellers made of wood which had been dried to the lowest possible moisture content, or bone dry, as they say in the forest products laboratory, the ends of the blades actually exuded sap, which was forced out by the centrifugal action. In tests, at least, it has been possible to speed the propellers up to such a pitch that the outer end of the blade on an 8-foot propeller travels at the rate of 400 miles an hour, says "The American Foresty Magazine," of Washington.

Some air-machine engines run at 1,700 revolutions a minute, and can be geared up to 2,000. An engine of this power would use a 9-foot 6-inch propeller, and the speed of the blade ends would be in the neighborhood of 600 miles an hour A good many thousands of pounds of pressure per square inch are generated by this action alone, and propellers have been known to split at the centre and fly apart. Even the smallest lack of balance between the two blades is very serious, since the pull of one must counterbalance that of the other.

### Wood Must Be Perfect

In addition there is the gyroscopic force which tends to keep the blades rotating in the same plane. At high speed this force is hard to overcome, and the cross strains it introduces when there is a change of direction, either up, down or sidewise, are enormous.

Yet under conditions of modern warfare, when an aviator has to "loop the loop" or plunge, or ascend sharply in manoeuvring to bring down, or escape from an enemy, the machine has to meet and withstand these unusual tests.

Wood for aeroplane manufacture must be 100 per cent. perfect. In other articles there may be a slight margin of [illegible] recognized in lumber grading rules. In aeroplanes, however, the safety of the aviator and army demands entire freedom from flaws. Even with Sitka spruce, the favorite wood for aeroplane construction, there is difficulty in obtaining the very highest grades. The United States Forest Service estimates that only 13 per cent. approximately is available for plane construction. Of Port Orford cedar, 10 per cent. is about all that can be counted on as good enough for planes; about 8 per cent. can be used from the spruce of Virginia and West Virginia, and only about 5 per cent. from the smaller trees of Maine. A member of the Curtiss firm is reported to have said that only 167 board feet on an average goes into planes from each 1,000 board feet.

### Wastage is Very High

The quantity of wood needed for each 'plane varies, of course, with the size of the machine; few of the present-day types contain less than 250 feet, and it may take 2,000 feet in the rough to furnish this amount. One Washington lumberman is making sure of getting only the straightest of straight-grained stuff by splitting it out of the log instead of sawing it. He gets quality at the expense of considerable waste in riving out choice white oak cooperage stock or hickory for spokes. But the resultant product is sure to have straightness of grain. There is no place where this is more important than in 'planes.

There has been an actual dearth of the kind of Sitka spruce that must be had, but the North-western loggers and mill men, in spite of labor troubles, said to have been fomented by our enemies, have begun to catch up with the demand. Before long they should be able to keep up a sufficient and constant supply.

### Woods for Propellers

For propeller blades ash and white oak are used in considerable quantities, while some are made of mahogany, alternate layers of mahogany and spruce or mahogany and ash. Black walnut has been used in place of mahogany, because this wood does not splinter when hit by a projectile. Maple, birch and cherry have found some place in propeller manufacture. Douglas fir has been used in making frames.

## ENGLISH DEMAND FOR LEATHER BELTING INCREASES

BEFORE the war there was little opportunity for the sale of American belting in the Birmingham district. The trade was very carefully looked after by British manufacturers, who claimed that their product was the best in the world. They had the advantage of being on the spot, kept a large stock of their belts always on hand, and covered the country with active salesmen. Conditions now have materially changed. Government factories, munition factories and other establishments, not only in this country but also in France and other allied countries, are demanding greatly increased quantities of leather machine belting for their work, so that belting of this kind has come into great prominence in spite of the high price of raw material. The market demands belts of the very best quality, such as will do the work called for efficiently and without requiring too much attention. The best British belts fulfil these conditions.

### Effective Way to Sell Goods

The business should be placed in the hands of some one in close touch with the machinery industry who could give his whole attention to such products. The ideal way for an American firm would be to have its own representative over here to make a study of British terms and customs and carry a large stock. If a firm is not prepared to go to this expense, which, of course, would be considerable, then an agent should be selected from among the firms on the list that is forwarded. It might be advisable to provide for such a representative an allowance for advertising. It may be that London would be a better centre from which to work. In any event, there is a big opening in the United Kingdom for leather belts.

## MINERAL WEALTH OF ALSACE-LORRAINE

Frequent reference is made to the mineral wealth of Alsace-Lorraine, it being known that the invention of Thomas and Gilchrist turned that country into a vast gold mine, by rendering its iron ore useful and valuable. The German ambition is to secure also the great iron basin of Briey, the richest and most extensive of all Europe, estimated to contain from 3 to 4 thousand million tons of ore. Thirty miles away Nature has deposited 10,000 million tons of coal in the basin of the Sarre; east of Nancy, partly in France and partly in Lorraine, is one of the largest salt beds in the world; farther east, at Pechelbronn, is an oil district where 30,000 tons of mineral oil are extracted yearly; and finally, more to the south, near Mulhausen, is a wonderful deposit of potash, rivalling that of Stassfurt. Germany before the war was very poorly off for iron. In her own territory she had only 710,000,000 tons in sight. Her conquest of 1871 gave her a reserve of over two thousand million tons in Lorraine, but in spite of this she was lately obliged to import 12 million tons from Sweden, Spain, and Algeria, and was looking to Morocco to aid her supply, whence the "Agadir affair."

## SUPPLIES OF GASOLINE

IN 1915, Canada consumed over 43,000,000 gallons of gasoline. Of this amount about 5 per cent. was produced from Canadian crude, while the remainder was either imported direct or produced from imported crude. This fact shows the dependence of Canada upon supplies of gasoline and petroleum from United States and strengthens the argument used in a previous issue wherein it was stated that 20 per cent. of the gasoline used in Canada was produced from Canadian crude oil.

# Modern Economies in Pickling Steel*

y J. H. Snyder **

*Increased costs in labor and materials have been so continuous and widespread that few branches of engineering industry have not been compelled to devote more than ordinary attention to every opportunity for effecting economies. Increased use of machinery and care in the choice and strength of acids to insure uniform and reliable work are advocated.*

DURING the last five years, and more especially the last two years, on account of the rapid rise in the cost of labor and acid, practically all the larger plants and many of the smaller ones have made efficient changes in their pickling department to reduce labor and acid consumption, increase output and get a more uniformly pickled product. Experiments have been made with solutions of potash, Wyandotte cleaner, etc., to eliminate oils and grease preparatory to the acid bath, thereby saving a large percentage of acid.

### Increased Use of Machinery

Conveying machinery, trucks, cars cranes, etc., have recently been installed to increase output. Wire is now frequently sent from the mills to the cleaning departments on an endless chain conveyor, with hooks spaced at suitable intervals for holding the wire coils. Ordinary factory trucks are often used to transfer sheets, tin plate, forgings, pipe, castings, etc. Sometimes, where conditions are suitable, tracks are laid throughout the plant with switches and turntables and cars convey the material over these tracks to the different departments. In large plants electric cranes are used for carrying material to and from the cleaning department. Devices are attached to the crane hooks for carrying each particular product, thereby effecting an efficient means of transfer.

Electric hoists, air hoists and jib cranes assist the men to place and remove material being cleaned in the vats, and also to shift this material in the acid solution to obtain better results in cleaning. In many cases large electric cranes, used in the transfer of the production from one department to another, are used for this purpose. This method, used in several plants with more or less favor, has the following objections: The acid fumes constantly rise and come in contact with the electrical apparatus, causing increased maintenance cost and delays in operation; the objects lie motionless nearly all the time in the acid solution, which, on account of little or no agitation, is of varying density from bottom to top, so that certain portions of the objects are overpickled and other portions contain unpickled spots.

### Types of Pickling Machines

Many companies have installed pickling machines to take the place of electric cranes and reduce the labor. These machines are to a great extent acid proof, simple in design and fool proof in operation. The surging or plunger type, which has been in use a number of years, forces the acid up through the material being pickled by means of a plunger. This keeps the density of the acid throughout the vat constant. The machine is installed where an extremely large tonnage is desired and seems a great improvement over former methods, but since the material is not agitated the greatest economy is not reached.

A machine made by the Mesta Machine Co. agitates the material as well as the acid by moving the load up and down through the different solutions and is being used for almost every kind of product that is being pickled or cleaned. The machine is operated by steam or air from a central plunger carrying horizontal arms from which are suspended acid proof crates. The number of arms is governed by the number of baths required.

Pickling, rinsing and loading are all done simultaneously. Sudden admission of steam or air in the cylinder at the end of the down stroke of the plunger causes a snap which tends to separate and shift the material so as to remove the scale or sand, scour the material and mechanically aid the chemical action of the acid. The advantages of this machine are: Crane service can be eliminated; labor can be materially reduced; acid required per ton pickled can be reduced; it is simple in design and fool-proof in operation; exhaust steam can be used for heating the vats; maintenance cost is low, and small floor space is required.

### Acids and Pickling Compounds

To have ideal pickling the scale and oxides should be removed without any chemical action on the metal directly beneath them and great care should be exercised in the choice and strength of acids so a maximum cleaning action may be obtained with a minimum solvent action on the metal.

Acids used for pickling are sulphuric, muriatic or hydrochloric and hydrofluoric. Various compounds are also used. Sulphuric acid 60 deg. and 66 deg. Baume is most generally used in this country. It is generally admitted that sulphuric acid solutions clean metal as well as other acid solutions if made strong enough to remove all scale with sufficient rapidity not to allow any part of the material to become overpickled, or combined carbon to precipitate and form a graphite coat on the surface.

The proper percentage of sulphuric acid necessary is governed by experience and is controlled by the character of the material to be pickled. According to Comey (Dictionary of Chemical Solubilities) the rate of corrosion increases with concentration of acid up to a certain point, after which the rate of corrosion decreases. This variation is sometimes very irregular with different materials. The action of acids also increases by raising the temperature. Most men mixing solutions guess the amount of acid necessary; some test with the hydrometer, others tell by taste the strength of a solution.

Many companies change the sulphuric acid solution every 24 hr. When work is begun in the morning a solution of about 8 per cent. sulphuric acid by volume is put into the vat and the proper amount of water is mixed with the acid. Throughout the day sufficient acid to keep the necessary strength is added. The vat which contains scale and ferrous salts is cleaned out completely and a new solution made for the next 24 hr. This is done where large tonnages are pickled. In most of the plants acid is added for two or three days, or even much longer than this, and from time to time the scale is cleaned out and some of the weakened acid solution drawn off.

### Use of Potash

Where the material to be pickled is covered with oil or grease potash solutions are used to clean the surfaces. Potash is very expensive and a substitute known as Wyandotte Cleanser is used. It is claimed that 50 per cent. sulphuric acid is saved by proper cleaning of material preparatory to the acid bath.

Some substitutes used in place of sulphuric acid and in connection with it are Edis Compound, Kleanrite, Nitre Cake, etc. Edis Compound is manufactured in dry cakes which are soluble in water. The temperature of the solution is kept about the same as with acid. Kleanrite is a powdered compound, and is ordinarily used in a solution made up of 1 lb. of Kleanrite to 4 or 5 lb. of water. This solution may be varied to suit the character of the material. Nitre Cake is also used in a similar way. About 1 lb. is used per gal. of water. The substitutes have met with favor in some plants and it is said that they do not emit disagreeable fumes, such as is the case when pickling with sulphuric acid.

The amount of sulphuric acid per ton of steel pickled varies with the character of material and with the chemical analysis of the acid. It ranges from 60 lb. to 200 lb. per ton of steel. Arsenic is very detrimental in sulphuric acid, and if one-tenth of one per cent. is contained in the acid, pickling is hindered to a considerable extent. A great deal more acid

*A paper read before the American Drop Forge Association

[illegible] sulphuric acid and there is a tendency to more acidity in the former [illegible] Hot water, one contains per [illegible] with 66 deg. Baume acid. Considering the low cost of this acid this should be used as fast and for the same cost per ton as with 66 deg.

### Correct Temperatures

The temperature of the sulphuric acid solution should be kept as near the boiling point as possible. In various plants the temperature varies from 75 deg. F. to 212 deg. F. For hand pickling the temperature is generally preferred low on account of the danger of having a hot open acid vat into which workmen may fall. Usually where this method is used ventilation is very poor and laborers cannot work efficiently because of the steam. The temperature of the bath frequently is obtained by connecting a steam pipe to the vats from the low pressure boiler used for heating the office buildings, shop offices, etc. This necessitates long steam lines and the vats usually get what is left when all other requirements are provided for.

The usual practice in plants of ordinary size is to pipe live steam into the acid solution. In this case a great saving can be effected when pickling with a steam-operated machine by piping the exhaust steam through an oil separator into the vats. In some cases, especially in smaller plants, anti-acid coils are used to which steam is admitted, and in this way the solution of acid is not weakened by condensation of steam.

High temperature has a remarkable effect on the efficiency of the chemical action of the acid and it is extremely detrimental to good work, as well as extravagant in acid consumption, to use a lukewarm solution of sulphuric acid. On the other hand, it is claimed that when the bath is kept too hot a large amount of finely divided acid is carried up in the vapor which corrodes the structural steel of the building and, in time, may cause serious trouble.

The temperature of water in the vats is a problem which everyone must work out for himself, being governed entirely by the kind of material to be washed. Certain materials require cold water, while others require it as hot as possible. For instance, enameled ware is immersed in cold water, while sheets in heavy gages are rinsed in very hot water and allowed to dry from the heat thus absorbed. But [illegible] gage sheets must be put through a drying furnace to prevent rusting.

The following table shows the varying amounts of sulphuric acid by volume and the time necessary for successful pickling, together with the method used as a basis for the figures given:

| | | Average Pickling Time in Minutes | Method |
|---|---|---|---|
| [illegible] | [illegible] | 6-10 | Machine |
| [illegible] | [illegible] | 10-20 | Hand |
| [illegible] | [illegible] | 8-12 | Machine |
| [illegible] | [illegible] | 10-20 | Hand |
| [illegible] | [illegible] | 15-30 | Machine |
| [illegible] | [illegible] | 25-50 | Hand |
| [illegible] | [illegible] | 10-15 | Machine |
| [illegible] | [illegible] | 20-25 | Hand |
| [illegible] | [illegible] | 12-15 | Machine |
| Cold rolled steel . | 10-15 | 20-25 | Hard |
| Stamping | [illegible] | [illegible] | Machine |
| [illegible] | [illegible] | 8-10 | 15-18 | Machine |
| [illegible] | [illegible] | 15-20 | 20-30 | Hand |
| Enameled ware .. | 10-15 | 15-20 | Machine |
| [illegible] | [illegible] | 10-15 | 25-8 | Hand |
| Alloy forgings ... | 8-10 | 20-30 | Machine |
| [illegible] | [illegible] | 8-10 | 30-45 | Hand |

After the material is properly pickled it is transferred to the water bath, where the acids and ferrous salts are completely washed off.

### Vat Construction

Vats used for pickling solutions are made of white pine, cypress, California fir, birch, concrete, anti-acid tile brick and other material.

The most preferable material at present is No. 1 white pine, although it is somewhat expensive and difficult to get. When a vat is properly constructed from this material an average life of from two to four years is obtained. There are companies using concrete vats lead lined, wooden vats lead lined, and anti-acid tile brick with success. However, the cost of a vat made in this way is more than that of the ordinary wooden vat, and it is a question whether the added life justifies the extra cost.

A good construction of a wooden vat is to use 6x6's or 6x8's or 8x8's, painted with thick white lead and rabbeted together with copper bolts put down through the center. A false lining on the walls and the bottom of the inside of the vat is made of 1-in. match white pine. Guards made of 2x4's or 2x6's are placed up and down in the vat at different points to protect the lining. This lining is the only part of the vat that must be removed and repaired.

In the use of concrete tanks it is best to lead line them to keep the acid from being continually in contact with the concrete. Also, concrete chips very easily when struck by the crates while handling the material.

### Features of Ventilation

An important factor in the pickling department is proper ventilation of the pickling room. The suggestion usually made is to construct a high building with a ventilator on top containing a double row of windows. This, however, is not the best method. When volumes of vapor rise in winter weather they are met with a strong current of air from the windows above, since cold air rushes into the room instead of allowing the warm vapor to wend its way out.

A well ventilated pickling room, not over 15 ft. high, has a single row of windows on one side of the building, slightly higher than the top of the vats. A small fan placed in the window opposite each acid vat induces a continuous volume of vapor and acid fumes, coming directly from the surface of the acid vat, to pass through it. Thus practically no vapors or fumes are left in the pickling room. The temperature of the room is about 60 deg. Fahr. and it is important to keep it at least this high. It is customary in many plants to provide little heat to the pickling room and in winter workmen are forced to grope about amid clouds of vapor at almost a freezing temperature.

Another excellent method of ventilation is to take in cold air through a series of hot steam pipes and then force it up into a large horizontal pipe which runs along the pickling room about 15 ft. above floor level. In this horizontal pipe are several down comers, through which the hot air passes. The temperature is maintained at from 60 deg. to 70 deg. to prevent the formation of vapor. The fumes are forced up by the warm air and pass out of the building through a single row of windaws at the top. Another system forces air up through pipes placed near the floor level at an agle of about 45 deg. on the opposite side of the room from the vats. By this method, not only is the room heated in winter and cooled in summer, but the rising fumes are caught, taken up by the blast of air and carried out of the ventilator.

When a pickling department must be laid out in a large building containing machinery, a very good method is to build semi-circular brick walls around the vats, which tend to carry the fumes up 20 or 30 ft. A fan placed in a ventilator above will conduct them out with comparatively little damage.

### Pickling Versus Sand Blasting

In the drop forge industry, pickling, tumbling and sand blasting are the three principal methods used in the cleaning department. Pickling is preferable if the acids and salts are thoroughly washed from the surfaces of the forgings.

Information received from one of the largest companies in the country shows there is no favorable comparison between pickling and sand blasting. In the former method all surfaces are cleaned thoroughly from oxides or foreign substances which are detrimental to the machining operation, while in the method of tumbling and sand blasting, small forgings, tumbling together, hammer fine sand into their surfaces. The resulting cost of machining is 300 to 400 per cent. more than that of pickled forgings. Furthermore, drop forgings containing small bores or indentations are not cleaned properly by sand blasting. The same authorities claim that all companies in the drop forging business eventually would pickle their product, as the additional cost is more than offset in machining.

In this connection the reclamation of waste acids for the manufacture of copperas is important. In one instance a company allowed waste acid to flow down the river for years and later reclaimed it with a net profit of $60 per day. Comparatively few companies are doing this at present and these only experimentally. Within the next decade this by-product will be generally made throughout the country.

## FUEL RESEARCH IN BRITAIN—I.

FOR some time the Department of Scientific and Industrial Research has been conducting an investigation through its Fuel Research Board into the coal situation in Great Britain. They had in view two main lines of research:—(1) A survey and classification of the coal seams in the various mining districts by means of chemical and physical tests in the laboratory, and (2) an investigation of

the practical problems which must be solved if any large proportion of the raw coal at present burned in its natural state is to be replaced by the various forms of fuel obtainable from coal by processes of carbonization and gasification.

The first report to be published by the board was made public recently. It is signed by Sir George Beilby, Director of Fuel Research, and describes the scheme of work which has been adopted and the plans which have been drawn up for the establishment of a fuel research station on an industrial scale at East Greenwich. At one time it was thought that the first line of inquiry could be proceeded with in advance of the second, but further consideration has shown them to be so interdependent that they can be most satisfactorily dealt with side by side. However, in preparation for the organization of the first line of inquiry, an experimental study of standard methods for the examination of coal in the laboratory has been made, and as the result of work carried out for the board in the Fuel Laboratory of the Imperial College of Science a test has been elaborated which, by direct weighing and measurement, gives the yields of gas, oil, water, and carbonaceous residue that result from carbonization at any definite temperature.

As regards the collection and registration of samples from different coal-mining districts the representatives of the coal owners have shown every disposition to co-operate; but it is not proposed to start any extensive organization for this purpose until the preparations for the second line of inquiry are further advanced, since the accumulation of large numbers of samples would serve no useful purpose at present and would be decidedly inconvenient.

### Problems of Carbonization

Various influences during the last eight or ten years have led up to the second line of inquiry, including demands for cheaper and more ample supplies of electrical energy, for home supplies of fuel oil for the navy and of motor spirit for the transport and air services, and for smokeless domestic fuel. The only development that would satisfy all these needs simultaneously would be the replacement of a large proportion of the raw coal which is at present burned in boilers, furnaces, and domestic fires by manufactured fuels prepared from raw coal by submitting it to distillation. A certain amount of knowledge and experience is in the possession of experts, who might be able with its aid to organize and direct schemes for replacing raw coal by manufactured fuel in certain directions and on a fairly large scale, but no really comprehensive scheme can be formulated until certain perfectly definite problems in coal distillation have been solved.

The gas retort and the coke oven have become highly developed appliances for the carbonization of coal at temperatures ranging from 900 to 1,200 deg. C.; accordingly, for such high temperature methods of carbonization a great amount of experience is available, and trustworthy data on which to base the calculation of the economic possibilities are in existence. But for the carbonization at lower temperatures there is no corresponding body of experience, and very few properly accredited data are available; for, although the low temperature distillation of oil shales for the production of mineral oils, paraffin wax, and ammonia is a highly developed industry, the oil shales are totally unlike coal in their nature and the products they yield, and experience gained in that industry is only indirectly useful so far as coal is concerned. Of the experience gained in low temperature carbonization of coal by individual inventors and syndicates only portions have been disclosed, but enough is known to justify the conclusion that much still remains to be done in devising the special forms of apparatus required for carrying out this type of carbonization. The way is obviously open for a serious attempt to determine whether economical and efficient apparatus can be devised for this purpose, and whether, by using properly selected coals in such apparatus, products will be obtained of a collective value greater than that of the original coal plus the cost of carbonization and handling.

### Questions to be Answered

The solution of these fundamental problems will supply a new base from which to attack such questions as the following:—

(1) Can the 35 to 40 million tons of raw coal used every year for domestic heating be replaced wholly or partially by smokeless fuel, solid or gaseous, prepared by the carbonization of this coal?

(2) Can adequate supplies of fuel oil for the navy be obtained by carbonizing the coal at present used in its raw form for industrial and domestic purposes?

(3) Can supplies of town gas be obtained more economically and conveniently by methods of carbonization and gasification other than those now used in gas works?

(4) Can electric power be obtained more cheaply if the coal used for steam raising is first subjected to processes of carbonization and gasification?

(5) Will the more scientific development of the preparation and use of fuel, which would be implied in the successful working out of the foregoing questions, enable the peat deposits of the United Kingdom to take a serious place as economic sources of fuel for industrial purposes?

(6) Can the use of gaseous fuel in industrial operations be forwarded by the development of more scientific methods of combustion in the furnaces, muffles, and ovens used in metallurgical, ceramic, and chemical operations?

Answers to these questions, the report points out, will be obtained only by coordinated research carried out on the lines of a broad and well-considered scheme; but at the same time the Fuel Research Board think it is to be expected that solutions of some of the problems will be supplied by workers in the industries, and they would regard it as a great misfortune were the establishment of a Government organization for fuel research to result in discouraging or in any way limiting the activities of outside workers or organizations.

### Disposal of Products

Even if an efficient method of low temperature carbonization is evolved it will be valueless in the wider sense unless profitable outlets for all the important products can be developed; and the Fuel Research Board, being in official touch with the Admiralty, the Ministry of Munitions, the Board of Trade, and other public departments, is exceptionally well placed for the furtherance of schemes that entail the finding of large outlets for products new and old. For instance, since the Admiralty attach great importance to the development of supplies of fuel oil from home sources, this requirement alone would absorb all the oil which could be produced by the carbonization of tens of millions of tons per annum. This fact alone gives an entirely new aspect to the extension of carbonization in hitherto untried directions, but while it will undoubtedly help on the economic side of the problem, it does not relieve the pressure on the technical side. In a way, moreover, it accentuates the problem of the profitable disposal of the coke which is left when the volatile products have been distilled off the coal. On the average it may be taken that each ton of coal carbonized will give 15 cwt. of coke; hence from the 20 million tons of coal which would have to be carbonized in order to obtain one million tons of fuel oil for the navy 15 million tons of coke would be produced.

The disposal of this large quantity of coke at a profitable price must be regarded as the vital question if low temperature carbonization is to be established on a sound economic basis. The research scheme must, therefore, include a very complete inquiry on the use and value of this coke for the direct firing of steam boilers, its gasification in producers for the manufacture of low-grade fuel gas and the recovery of its nitrogen as ammonia, and its use for industrial and domestic heating, either directly as it comes from the retorts or after conversion into briquettes. The second of these inquiries will involve the development of a special form of gas producer and auxiliary plant if the best results are to be obtained, and also of a system of boiler firing in which fuel gas of low calorific value can be burned at least as efficiently as coal, both as regards thermal efficiency and the effective evaporation per square foot of heating surface.

The use of the lower grade of fuel gas, though successfully carried out in certain directions, is very imperfectly understood in the majority of industries in which gas might be used for heating and power purposes, and here there is scope for much useful work, both in research and in the education of experts and consumers. Again, though the use of town gas as a fuel for industrial purposes has made great strides during the past few years, actual practice still lags a long way behind the ideals of economy and efficiency.

## MULTI-MACHINE OPERATION

TEN or fifteen years ago extensive controversy existed respecting the ability, possibility or advisability of one workman operating more than one machine. By this method it was proposed—often successfully—to reduce the labor cost of manufacturing. It was, however, the cause of considerable contention and lengthy discussion, particularly on the part of organized labor, this dissension seldom affording a fair trial for the two-machine-per-man idea. It is therefore interesting to note the change that has come about between then and the present time, where, with the exception of automatic and semi-automatic machines, the manipulation of metal working tools is invariably limited to one machine to each operator. This condition has resulted more from the development and improvement of the equipment and the cutting tools rather than the failure of the system and its possibilities. Under the former labor-saving idea it was practicable to so arrange two or more machines (millers, planers, lathes, etc.), that the workman could conveniently and economically operate such tools to good advantage, having complete control of the mechanism by merely turning around, or taking a few steps.

The factor that has been largely responsible for the gradual elimination of the multi-machine practice is the development of high speed cutting steel, supplemented by the corresponding evolution and improvement in machine tools to meet the requirements demanded by the heavier cuts and feeds that are possible by the use of modern high speed steel. It is not that the tool steel or machine tool evolution is the actual cause of the change noted, but the relation that these factors have to the cycle of operations. The achievement of high speed steel has altered the ratio between the setting-up and actual cutting times, the former in a great number of instances being the same as always, while the latter has been reduced to the minimum. In former days it was possible to utilize the time occupied in taking a cut over the work in setting-up a similar job in another machine, the setting-up occupying about the same period as the machining of the work. The heavier feeds and greater speeds of recent years have enabled the actual cutting of the metal to be performed in much shorter time, so that it is now seldom possible for an operator to leave the work long enough to set up a job on another machine. With the constant advancement in the design of machine tools—other than those of the automatic variety—and the corresponding development of cutting tools, the future possibilities of multi-machine operation are small.

## CONSERVATION OF FUEL

PROMINENT among the many problems with which manufacturers have to contend at the present time, under the stress of economic production, is that of the conservation of fuel owing to the failing of the immediate supply available for industrial and domestic purposes. Existing conditions make it almost imperative that every possible means be adopted to avoid unnecessary consumption or waste of fuel. Measures may be taken, however, to minimize the use of coal to the detriment of other vital and equally important factors of shop or factory operation. Under present circumstances, with a very evident scarcity of fuel, manufacturers may be tempted to forego the heating of their plants during the idle period over the week-end and a corresponding reduction each night. It may seem ridiculous to maintain a fairly warm temperature in a shop from which the workmen are absent for a period of from 24 to 36 hours. While the fuel saving from such a practice would undoubtedly be of considerable importance, it might be well to give more than passing attention to the possible consequences incidental to the unavoidable fluctuation of working temperature.

In many factories or workshops the heating is accomplished by the circulation of the exhaust steam from the engine; in others, the system may be supplied from the live steam from the boilers, or by means of forced hot water or hot air circulation. In any case it is often found that the closing hour is not only a signal to the workmen to knock off, but may also indicate the closing—in whole or in part—of the valves that control the passage of the heating medium from the source to the different "unoccupied" portions of the plant. It is, however, considered advisable, particularly in very cold weather, to always permit sufficient steam or hot water to pass through the pipes to prevent the possibility of freezing. This invariably eliminates piping troubles but creates other contingencies having vital bearing, although seemingly unimportant relation, on the output of the shop.

Early on Monday morning—sometimes after the men have started work—steam is forced through the heating system to warm up the shop, and after a period ranging from ten minutes to perhaps a couple of hours the atmosphere is quite comfortable; but what of the equipment? Metal machinery, especially of a bulky character scattered about a spacious shop, will seldom attain a very high temperature, even in summer weather, unless subjected to the heat of an adjoining furnace or other radiating unit. When the workmen leave a factory and the heat is partly or entirely shut off the proportionately large volume of metal rapidly absorbs the heat from the atmosphere, and then continues to fall until the return of the men in the morning, when the machines are like so many blocks of ice. This order of things is not conducive to an early start, as the men seldom show any great desire to freely handle the cold equipment.

Apart from the evident inconvenience to the operators, the fact that unavoidable delay may be necessary in getting a machine into action, a cold shop is a thing to be avoided. Where accuracy is a feature of the work, and rigid inspection is adopted, it is essential that extreme variations in shop temperature be avoided as far as possible. Under these conditions normal temperature is a very important and necessary factor. Even confining the question to the actual saving of fuel, the result may be open to discussion, owing to the additional initial firing that is necessary to disseminate sufficient heat to meet the shop requirements.

# INDUSTRIAL NOTABILITIES

# Traffic Congestion and Severe Weather Reduce Production

*Weather Conditions Intensify Difficulties Due to Railroad Congestion—Iron and Steel Situation Continues—Prices Are Firm With Unsettled Outlook*

TRADE has been demoralized by the severe weather which tied the railways up and rendered the movement of freight almost impossible for two or three days. The most serious aspect of the situation is the shortage of coal and coke which is worse owing to the delay in moving cars from the border. Industrial activity is being hampered by the scarcity of coal and little relief may be looked for until the weather moderates for a long enough period to permit sufficient coal to be transported. The steel plants have suffered severely by the stormy weather which has not only made operating conditions very difficult but has also prevented the shipment of coke and other raw materials to the mills, so urgently required. No further announcement has been made in regard to the Dominion Government's contemplated action in regard to increasing the production of iron and steel. Plans are doubtless being prepared and some definite announcement will likely be made in the near future. In the meantime the shortage of iron and steel is becoming more acute, with little prospect of immediate relief. Steel prices generally are holding firm, although Canada plates and galvanized sheets have declined. Pig-iron prices are firm and unchanged but the outlook in the market is unsettled owing to the coke situation. In the non-ferrous metal markets lead has advanced following a strong situation for some weeks. The fixed prices of copper have been extended for an indefinite period. Tin continues in short supply and prices are entirely nominal. Solders have advanced. Prices of machine shop supplies are firm and some advances have been made affecting coal oil, fuel oil, castor oil and cotton waste. The machine tool business is more active, the demand being mostly for equipment for shell production.

MONTREAL, Que., Jan. 14, 1918.—Industries generally have been hard hit during the past week by the extreme stormy weather that has been prevailing and still continues throughout a large area of Canada and the United States. Railroads are unable to cope with the situation, and traffic is practically suspended in various sections, and in consequence business has been very much demoralized by the non-delivery of much needed materials, which in many instances has necessitated the closing down of plants until these conditions are relieved. Many factories in this district have been badly hit by recent storms, and have had to curtail production in order to conserve their already declining supply of fuel, a condition that may be further emphasized in the very near future. An encouraging note is sounded in the attitude of the Canadian Government towards the increasing difficulty that is apparent in the steel situation, and steps have been taken to investigate the possibilities of increasing the present available supply of steel, particularly ship plates, by construction of additional facilities for the manufacture of this and other essential steel products.

### Pig Iron

In common with all other industries the pig iron furnaces are suffering through the inability to obtain sufficient fuel and other raw materials to operate at capacity, with the inevitable result that banking of furnaces has been necessary, consequently curtailing the output. This condition is general both here and in the States, the severe weather making it almost impossible to get shipment over the railroads that have been affected by prevailing storms. Negotiations are now in progress between the Canadian and American Governments in an effort to get additional pig iron into Canada to relieve the situation that threatens to become very acute. Canadian producers are virtually out of the market and little local iron is available; dealers here are not quoting, as the market is a nominal one.

### Steel

It has been practically settled that no immediate or early revision will be made in the prices now ruling in the primary markets. While many have looked for some further action on the part of the American Government in this connection, the consensus of opinion appears to be that the production and sale of steel products are now carried on under a basis satisfactory to all. Manufacturing conditions have recently been handicapped owing to the continued unfavorable weather that has been prevailing throughout those sections of the country where the greater portion of the steel trade is carried on. Railroads in general are fighting the heavy snowstorms and transportation facilities are insufficient to cope with the difficulties of the situation, with the result that much needed materials are delayed in transit, and consequently creating serious conditions in many industries. The situation in the States has become increasingly acute owing to the utter impossibility of obtaining delivery of necessary supplies; many furnaces have been banked, and mills have been forced to close down temporarily until milder weather releases the freight that is tied up in all sections of the country. Recent storms have materially increased the congestion that has been more or less pronounced for many weeks. A notable feature at present is the crowded condition of many of the Eastern seaports owing to the inability to obtain ample cargo capacity for the export of materials. Everything possible is being done to conserve the available supply of coal so that essential industries will not be seriously affected.

The Canadian situation is virtually a counterpart of that prevailing in the States, as manufacturers here are dependent upon American mills for the bulk of their material; with very few exceptions all imports of iron and steel products must be made under license, and practically no non-essential material is obtainable under any circumstances. Weather conditions have added to the difficulties of the situation here, as the recent heavy storms in the great lakes territory have greatly demoralized railroad and industrial business, with the result that the situation now is more acute than ever before. While consideration is being given by the Canadian Government, with a view of relieving the iron and steel scarcity here, particularly in connection with the ship plate situation, any action in this connection would necessarily require some time, so that the immediate future offers little improvement over prevailing conditions. Dealers here report little or no change, and price quotations are nominally unchanged but firm at figures previously quoted.

### High-Speed Steel

Business of considerable volume is still being done in high-speed steels, and the difficulty appears to be to get sufficient of the better grades to supply the demand. The importance of this branch of the steel industry is reflected in the announcement of one local dealer, who has orders on his books for thousands of dollars' worth of high-speed steel at a price of $2.40 per lb., but is unable to fill them owing to the impossibility of getting permits to ship the same from the English works. This firm, or rather the Canadian agency, are able to secure steel of a lower grade from American manufacturers, but which is not suitable for the same purposes as the high-speed steel. The general demand for high-speed steel continues to be of an encouraging character, the price ranging from $2 to $2.50 per lb.

### Metals

With the exception of tin, the metal market is featureless owing to the unsettled condition that seems to prevail regarding the possible action of the Am-

erican Government in reference to further price fixing. Weather conditions have materially affected the delivery of metal to many points, but supplies in stock have invariably been sufficient to carry over any temporary difficulty like that of the past week or so. Copper continues firm at regulation prices. Tin has again become the centre of interest following the sharp return of strength on the London market, which has created a nervous condition on this side. Spelter is quiet and unchanged. Lead is unsettled, but relatively firm. Antimony remains quiet, with quotations firm. Aluminum is unchanged, but stronger in tone.

**Copper.**—Satisfactory conditions appear to prevail throughout the copper markets and the supply seems to be sufficient to cover the requirements of all those consumers that are engaged on essential war work. Some fears have been expressed that production may necessarily have to be curtailed owing to the great difficulty that now exists in maintaining the regular delivery of materials necessary for the continuous operation of the refineries. So far, however, no serious effect has been apparent, and it is hoped that relief in this direction will be given before conditions become acute. Jobbers continue to do a good business on the concession granted for the disposal of small lots of metal. The general situation is harmonious in character, and little is now heard of further revision of the regulation price. Dealers here report an active market, with quotations firm at 32c and 33c per lb.

**Tin.**—With the London market reacting again to higher position the tendency has been to resume the nervousness experienced before the British decline. With the sharp falling off noted last week in London the tone of the New York market was decidedly easier although few sales were recorded at prices below the nominal figure of about 85 cents per lb. Nothing definite has been given out as to the actual cause for the sudden reaction but it is thought that certain regulations in connection with the permit problem is primarily responsible. Owing to the marked shortage of Straits tin considerable business has been done in Chinese and Banca. The New York market is very unsettled and nothing reliable can be obtained as to the future of this metal. Under the present difficulty that surrounds ocean transportation the market on this side will continue very strong. Local dealers report a good demand and a return to last week's quotation of 77 cents per lb., an advance over the recent price of one cent per lb.

**Spelter.**—Nothing of interest to report and the market is comparatively quiet, more so than a week ago. Business is dull in New York and the market is inclined to be weaker. The situation here is practically unchanged but price quotations are fairly well maintained; dealers are asking 10½ cents per lb.

**Lead.**—The recent strength that was announced on the New York market was more for the purpose of making the situation more uniform than actual strength of general conditions. An unseen and equally unexplainable conflict appears to characterize the transactions in lead and under such conditions the market is more or less unsettled and will continue so unless the Government takes steps to put this metal on a basis with others now under certain regulations. The American market is firm at last week's quotation; the situation here is unchanged but showing an easier tendency; prices are unsteady at 9¾ cents per lb.

**Antimony.**—Some little interest has been shown on the American market over the announcement of considerable buying on the part of the Government but it has failed to develop any strength that would be reflected in the price quoted on the open market. On the contrary, the situation has a tone of weakness with the market slightly lower. The local market is quiet with quotations unchanged at 18 cents per lb.

**Aluminum.**—This metal is in steady demand and the market appears to be developing strength but the local quotation of 60 cents per lb. is firm and unchanged.

**CANADIAN GOVERNMENT PURCHASING COMMISSION**

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

### Machine Tools and Supplies

While the local machine tool business is still comparatively quiet the activity in general equipment has shown a little improvement; these inquiries and sales have been more for shapers, millers and drilles than for lathes. One local dealer, however, reports that he has had several inquiries for machinery suitable for shell making, both for the six inch and the smaller sizes; it might be mentioned that these prospective purchasers are trying to obtain second-hand tools that are in fairly good condition and that can be obtained at a reasonable price. The continued demand for all class of equipment in the States makes it very difficult for Canadian dealers or users to obtain delivery of machinery under six to eight months, unless such tools are not in general demand. Canadian tool builders are quite active and are taking up new lines of needed machinery.

### Scrap

The situation in respect to old materials in the States has shown some improvement following the action of the Government in permitting the dealers to charge a commission of 3½ per cent. This has resulted in making the situation more settled as consumers are relieved from the anxiety of locating supplies and securing cars in which to transport the material from the source to the destination. Recent weather conditions have prevented the free delivery of scrap in many portions of the country, but locally the market has not been greatly effected as available stocks have been ample to satisfy the immediate demand. The market here is dull and business is light; machine cast iron and wrought iron pipe are both stronger, an advance of $2 per ton being noted in each case, the respective quotations being $27 and $17 per ton. Stove plate is easier by $2, the price asked here being $17 per ton.

## Toronto

TORONTO, Ont., Jan. 15.—The worst storm in years which passed over this district paralyzed the railways and as a result many factories and all steel plants have suffered much inconvenience. The shortage of fuel is particularly serious and many factories in this province are running on short time or closed down. It will be some time before the operating schedules on the railways can be restored to normal and in the meantime many industries will suffer.

### Steel

The volume of orders for iron and steel products is showing some improvement after the quiet period around the holidays but trade has been badly dislocated by the storm. For some days it was almost impossible to move any freight which aggravated the already acute situation in regard to the supplies of fuel. Work at the mills has also been hampered by the severe weather and the output will be curtailed as a result. There has been no further development in regard to the government proposals to increase the production of steel but it is understood that investigations are being made and plans prepared for some definite action on the part of the authorities at Ottawa. In due time some announcement will doubtless be made stating what the government propose doing. In the meantime all the available supplies of steel are going into consumption and the best is being made of a difficult situation. The tentative announcement issued in the first instance indicates a very ambitious scheme which will be difficult to accomplish. It is possible to increase the production of steel without much delay but the installation of rail mills and plate mills is a different proposition owing to the heavy cost and length of time that would elapse before the necessary equipment could be constructed and installed. The first thing that should be done is to ensure that the steel plants are provided with full supplies of raw materials, so that production may be kept up near the maximum [illegible] possible. Until this can be attained it is not [illegible] are enlarging steel plants for the new plants could not be operated

Canada plates and galvanized sheets, and discounts, but the result of the change does not show much material difference in the net prices prevailing previously. A readjustment has been over the previous list is an increase of $1 on ⅛ inch standard buttweld black, and an increase of $1.50 in galvanized standard buttweld of same size. Black ¼ inch and 2 8 inch standard buttweld have been reduced 2c per 100 feet, while the galvanized on same sizes has been advanced 7c per 100 feet. In regard to prices the market is very steady and will likely remain so for some considerable time in view of the ever increasing demand for steel which is tending to keep prices up. The situation in the United States in regard to supplies of steel has become more acute which will further tend to keep prices from declining. Across the line the exceptionally severe weather has tied up the railroads and prevented the shipment of raw materials urgently needed at the mills with the result that operations have been seriously curtailed and the trade demoralized. The unfilled orders on the books of the U.S. Steel Corporation on Dec. 21 amounted to 9,381,718 tons, an increase of 484,616 tons compared with the orders on Nov. 30. This is the first time that the monthly figures have shown an increase since April, 1917, when they were 12,183,083 tons, the cor-

### Pig Iron

Operating conditions at the furnaces have been most unfavorable this week on account of the severe weather and production has been seriously curtailed as a result. It has been almost impossible to bring coke in from the States and the shortage of fuel is more acute because of this. The Dominion Government has been urged by consumers to help in relieving the coke situation but in view of conditions in the States it is difficult to see what can be done. More furnaces have been banked in the States and others have gone out of blast. As an instance of this, only nine of the U.S. Steel Corporation's furnaces in the Chicago district are in operation out of 29. Conditions are about as bad in the Pittsburgh district.

### Scrap

The old material market continues dull and featureless and like every other industry has been affected by the tie up on the railways. Prices of scrap steel

tically all old materials are light, partly due to scarcity and also to the dealers' desire not to carry too heavy stocks on account of the unsettled state of mar-

### Machine Tools

business in the machine tool trade has brightened up a bit and the outlook is more promising. A number of shell plants have been buying equipment to balance up and to increase production. It is understood that the Imperial Munitions Board contemplate an expenditure of approximately $30,000,000 per month for several months which is about the same rate of expenditure that has prevailed during the last three or four months. Generally speaking the firms have had repeat orders but have not had the size of the orders increased. There are of course exceptions to this rule. One local firm is preparing to largely increase its production. The Dominion Shipbuilding Co., a new concern, is preparing plans for a five berth shipyard here. Considerable equipment will be required when the shops have been built. The Toronto Harbor Commission is interested in the construction of the plant. It is understood that contract for the buildings will be let shortly.

### Supplies

Business continued good and prices on a number of lines of machine shop supplies have advanced. A new price list for cotton waste has been issued showing an advance ranging from ½c to 1c per pound according to grades. Some lines are unchanged. An advance of 1c a gallon has been made in coal oil, Royalite being now quoted at 17c and Palacine 20c per gallon in bulk. Fuel oil is also up 1c and is now 13½c per gallon. Castor oil is now quoted at 52c, being an advance of 2c per lb. Cordage prices are very firm and an advance is expected in some lines on account of the situation in the raw material markets.

### Metals

An advance in the price of lead, extension of copper prices and more acute scarcity of tin are the principal features to note this week in the non-ferrous metal markets. The lead market has been gaining strength for some weeks which resulted in an advance in the primary market last week followed by an advance locally this week. The shortage of tin has become a serious matter for manufacturers who in many cases have been obliged to curtail production on account of their inability to obtain tin. There is no sign of improvement in the situation. News comes from Washington that the established prices of copper have been extended for an indefinite period. The announcement has had no effect on the market as it had been fully expected. Prices of solders have advanced owing to the high cost of tin and lead. Prices of the other metals are unchanged and quiet.

**Copper.**—It is understood that the established price of copper will be continued at 23½c New York for some time to come. While it was thought in some quarters that the arrangement between the Government and producers would continue until April 1, the more general conception of the program was that no definite time limit exists. The news did not occasion any surprise, as it had been forecast for more than a fortnight. The position of the copper market is unaffected by the news, and continues its routine course. Locally, lake and electrolytic copper are quoted at 32c and castings at 31c per pound.

**Tin.**—The tin situation has become more serious owing to the depletion of spot supplies and uncertainty in regard to futures. All tin afloat has already been sold and will at once pass into consumption upon arrival. Unless relief comes soon, some consumers will have to close down their factories, some having already had to curtail production. Prices are entirely nominal at 80c per pound.

**Lead.**—The lead situation continued strong and as a result the price has advanced ½c per pound. U.S. Government lead requirements are heavy but no information is being given out in regard to the purchases, and as a result there is some uncertainty in the market, although the undertone is firm. Lead is now quoted at 9c per pound.

**Spelter.**— The market continues quiet and more or less neglected, but producers are not anxious to make further concessions. Spelter is quoted locally at 10½c per pound.

**Antimony.**—The market is easy and prices are unchanged. The demand is light and supply sufficient for all requirements. Local price 18c per pound.

**Aluminum.**—The market is quiet and situation unchanged. Local price 62c per pound.

**Solders.**—Prices of solders have advanced in line with the high cost of tin and lead. Guaranteed is now quoted at 43c and strictly at 39c per pound.

## Sydney

SYDNEY, N.S., Jan. 11.—In the matter of the wage dispute between the Dominion Coal Company and the Amalgamated Mine Workers of Nova Scotia, upon the settlement of which dispute there admittedly hangs an adjustment of wage rates at all other Nova Scotian collieries, the Minister of Labor has despatched Senator Robertson and Mr. J. C. Watters as a Committee of Enquiry, and at the time of writing these gentlemen are in consultation with the leaders of the Amalgamated Mine Workers and expect to meet the representatives of the Dominion Coal Company. There appears to be some possibility of a compromise, and a Board of Conciliation may not be required.

### Company's Contention

The contention of the Dominion Coal Company is that there exists between itself and its workmen a wage contract which does not expire until the end of 1918. The company admits the necessity for an equitable adjustment of wage rates to meet the increase in the cost of living since the last adjustment in

May, 1917, and is of the opinion that the Commission which made the last-named adjustment should again be convened to review their previous findings. The Amalgamated Mine Workers for some reason do not apparently favor the reconvening of the previous commission, and have asked for a Conciliation Board. The visit of Messrs. Robertson and Watters is preliminary to the decision of the Minister of Labor as to the form of tribunal that is necessary to adjust the differences that exist. The increase which the Dominion Coal Company offered has gone into effect from the 1st of January, irrespective of the fact that no actual settlement has yet been agreed upon.

Production was badly affected by the snowstorms in Cape Breton at the New Year. For a week the Glace Bay Collieries of the Dominion Coal Company were idle or partially idle through the paralysing of transportation. The Inverness Collieries were similarly affected. The heavy snowfall was followed by heavy rains which caused numerous freshets and washouts, but had the favorable effect of clearing the railway lines more quickly than had appeared possible.

### Increased Production Impossible

It is stated the Fuel Controller intends to send a committee to Cape Breton to investigate the possibility of materially increasing the coal production. There is nothing that such a committee can do. A year ago much was possible, but the representations of the coal operators were not heeded. The fall of the Nova Scotia coal industry is to-day like that of Humpty Dumpty. Not all the King's horses nor all the King's men, nor all the Fuel Controllers in the world—and there seem to be quite a few—can restore the coal production of Nova Scotia during the further duration of the war. More than that, it is very doubtful if any action that the Government can take will even maintain present rates of production. Further diminution of coal production in Nova Scotia extending over a long period of future time is inevitable as sunrise.

## New York

NEW YORK, Jan. 12.—Conditions in the iron industry are deplorable. Fuel shortage, traffic congestion and railroad embargoes have caused demoralization at producing centers. Since Jan. 1, the industry as a whole has been operating scarcely more than 70 per cent. of capacity. In Eastern Pennsylvania eleven blast furnaces have blown out and six others are banked because of an inadequate supply of coke. Current production is scarcely 50 per cent. of capacity and productive costs at some furnaces have risen 20 per cent. above the selling price fixed by the Government. At Youngstown, Ohio, pig iron output is scarcely 50 per cent. of capacity and merchant furnaces in other sections are operating about 60 per cent. At steel plants, operation of blast furnaces is intermittent and as practically no supplies of pig metal are available in the open market the output of steel has been cut sharply. Even the U.S. Steel Corp. on some days has been operating only 60 per cent. of ingot capacity but improvement in the Pittsburg district is reported although there is still much irregularity at various subsidiary plants. The National Tube Co. last month operated only about 50 per cent. of capacity The corporation as a whole operated close to 80 per cent. of capacity in December, according to reports received on the 10th when the December statement was issued showing that shipments have been about 500,000 tons less than the new orders booked.

### Rolled Steel Demands

Buying of rolled steel products, thus far in 1918, has been confined almost entirely to Government orders placed on behalf of the Allies as well as to supply the needs of the United States army and navy. A most interesting development was the notification of the Government to the steel companies having bar mills capable of rolling sizes required in the manufacture of projectiles that almost their entire capacity will be needed for war purposes during the first half of this year. This is equivalent to stating that the mills will be required to roll 3,000,000 tons of shell bars by July 1. As half of this tonnage has already been ordered for the United States Government it is evident that 1,500,000 tons are required for export to Great Britain, France and Italy.

In the Central West, numerous additional orders have been placed for six and nine inch shells and other similar contracts are dependent upon manufacturers being able to secure the necessary shop equipment. The machinery industry at Cleveland, Chicago and Cincinnati, has taken orders for turret lathes and other tools for the manufacture of war munitions. Three manufacturers in Indiana, and two in Wisconsin have been awarded contracts for fuse parts and the tools needed have been purchased in the Chicago district.

### Record Crane Contract

Less business has been done in the Metropolitan district possibly because of delayed mails as many inquiries are coming by wire and a fair volume of business is being transacted. The Ordnance Department has placed a contract for hydraulic jacks for 9.5-inch guns with the Watson-Stillman Co. and the latter has purchased $100,000 worth of machine tools. There are also large inquiries in the market for lathes while the machinery division of the War Industries Board is asking Cleveland manufacturers for bids on 165 sixteen to twenty-four in. turret lathes to be shipped by April 1.

An official contract has been finally awarded to the McMyler-Interstate Co. by the Navy Dep't. for a 350 ton fitting-out crane to be installed at the Brooklyn navy yard. This will be the largest crane of this type ever built and the contract price is close to $800,000. The department is negotiating for two cranes of the same type for other navy yards. Following the placing of the contract for 8,000 tons of structural steel for the Government nitrate plant at Mussel Shoals, Ala., the Air Nitrates Corporation of N.Y., on behalf of the Government, has received bids on 15 cranes for this plant.

## Pittsburgh

PITTSBURGH, Pa., Jan. 12.—During the past ten days the Pennsylvania, Baltimore & Ohio and New York Central lines have declared more or less complete embargoes, refusing to accept freight for many points, excepting Government material, blast furnace raw material and perishable freight.

These embargoes almost completely prevent the Pittsburgh district from shipping its product, while the Youngstown district has only the Erie road to depend on, and it is partly embargoed. No statement is vouchsafed in railroad circles as to how long the embargoes will be kept on. They are strictly an emergency measure, calculated to relieve congestion, and are not directly an outcome of the Government having taken over the roads.

### Embargoes Affect Steel Mills

The steel mills cannot stock their product for any length of time, and within a week, if the embargoes continue, some curtailment of operations at finishing plants will be forced. Hitherto the iron and steel industry has felt results from the insufficiency of transportation facilities only in respect to receipts of coke and coal. The restriction in coke movement was such that pig iron production in the country dropped from a rate of 39,400,000 tons a year in November to a rate of 34,300,000 tons in December. The loss in production was chiefly in the Pittsburgh, Youngstown and lake front districts, which depend largely upon Connellsville coke, and the restriction in these districts has at times been as high

Strenuous efforts have been made along individual lines to improve conditions. Blast furnaces have employed many experts to work in the Connellsville region, routing shipments and frequently following them through to furnaces, also in discovering coke stalled en route and getting it started moving again. The railroads, by means of embargoes and otherwise, have sought to relieve the general congestion.

In this and other work that has been done there has been no co-ordination. Each interest has striven merely to improve conditions with respect to its own

over the railroads, at the close of December, there does not seem to be any comprehensive plan under consideration for utilizing the facilities of the railroads for various services in the order of their

doubt being done intelligently, is to relieve the congestion in general, whereby

[There will be a free movement of freight ... general.]

**Maximum Production Desirable**

The practical point is that full production by the iron and steel industry would pave the way for lower selling prices, if indeed it would not produce lower prices naturally by the operation of the law of supply and demand. Washington, it is well known, desires lower prices, the set prices now in force being the result of a voluntary agreement between the War Industries Board and the producers, Sept. 21, 1917, and being regarded as temporary. Originally they were set to run to the end of the year and when, late in December, it was decreed they were to continue to March 31 next, the postponement of revision was regarded as a necessity arising out of the circumstances and not as a particularly desirable thing in itself. With co-ordination between those in Washington who desire to see lower prices for iron and steel and the railroad system the way could be cleared for lower prices. Production costs would decrease and there would be more material to sell.

At the present time the whole situation as to production, prices and consumption is an extremely confusing one. Some plants are running full, some are running at restricted rates, and some are closed entirely, while there are changes from day to day.

**Steel Corporation Activities**

As to prices, the set prices govern, in nearly all instances, when there are transactions, but to all appearances the market is stagnant. Producers do not report making any sales to speak of, except to observe that they are receiving Government orders, and details of these are witheld, according to Washington's request months ago. This week, however, has come the puzzling fact of the United States Steel Corporation reporting an increase of 484,612 tons during December in its unfilled obligations. During the seven months preceding the Corporation had been reporting decreases, averaging nearly 500,000 tons a month. Shipments in December were curtailed by only 100,000 or 200,000 tons a month, and where the heavy bookings indicated came from is a mystery. Possibly the Corporation sprang a [illegible] and quietly booked some large tonnages with industrial consumers. If so, it must have offered inducements. A fact to remember in this connection is that in the Government's announcement of Dec. 29 that the set prices were to continue to March 31 there was a decree to the effect that any contracts made meanwhile should provide for price readjustment on any material delivered April 1 or later to any price that might subsequently be named by a Government agency. The Steel Corporation's December bookings would not be subject to that proviso, and buyers might find it [illegible] the matter of priority of deliveries, to have contracts

(Continued on page 72.)

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE—Valparaiso, British Consul General.

COLOMBIA—Bogota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Bahia, British Consul. Rio de Janeira, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

**CANADIAN TRADE COMMISSIONERS.**

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

**CANADIAN COMMERCIAL AGENTS.**

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum, Grubbegd No. 4 Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

**CANADIAN HIGH COMMISSIONER'S OFFICE.**

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

at above the Government prices ruling later.

There is practically no market to report at this time and the whole interest of the trade is as to what is going to

definite color. Deliveries on current contracts are behindhand in nearly all cases, and there is naturally no particular occasion for producers and consumers to enter into additional contracts. The striking fact is that, although production has been additionally restricted for several weeks past, there is no evidence that consumers are proportionately incom-

At no time for a twelvemonth or more has the industry operated at capacity, and the existing capacity, in both pig iron and steel, is much greater than the production has ever been. At the present time pig iron production is at the rate of about 33,500,000 tons a year, or approximately 9,000,000 tons less than the capacity, while production of steel ingots is at the rate of about 38,000,000 tons a year, or 10,000,000 to 12,000,000

The question is, what would occur if transportation conditions should be made such as to permit full production. The improvement in traffic conditions might conceivably increase greatly the consumptive requirements, but it would seem rather more probable that steel

## LIGNITE BRIQUETTES

THAT lignite coal briquettes can be laid down at many points in the Prairie Provinces, but more particularly in Manitoba, Saskatchewan, at a lower cost than anthracite, is the finding of the committee on minerals of the Commission of Conservation just made public. The report was prepared by W. J. Dick, mining engineer to the Commission, as the result of an investigation made by him into the possibilities of the lignite coal fields of Western Canada as a source of coal supply for domestic purposes.

Mr. Dick gives the following estimate of the saving which would result from the use of carbonized briquettes instead of anthracite in certain cities and towns in Manitoba, and points out incidentally that the price of anthracite is certain to increase. Portage la Prairie, nothing to 45c; Carberry, 80c to $1.30; Brandon, 85c to $1.10; Virden, 95c to $2.30; Moosomin, 95c to $2.20; Wolseley, $1.45 to $1.70; [illegible] to $2.50.

The estimated cost of laying briquettes down at Winnipeg is $10.50 per ton, or slightly more than the cost of anthracite.

## BRITAIN CUTS OFF EXPORT LICENSES

A FAR-REACHING announcement has been made by the representatives of the Imperial Government, having charge of the exportation to Canada of raw materials. It was stated recently that no more licenses will be granted for the exportation of raw materials from Britain. Those licenses issued up to November 30 hold good. The reason for this decision is given in the shortage of noils and woollens of all kinds for war purposes.

This decision will have a tremendous effect upon Canadian trade because of its great dependence placed upon shipments of wools and other raw materials from Great Britain. Whether this affects shipments from Australasia or not is not yet known. Canada has been receiving a lot of wool from the Antipodes, which have been the chief source of supply, and if this is cut off Canadian industries doing war and domestic work will be made to suffer a great deal.

## U.S. TO CONTROL FUEL OIL

THE United States Government will probably take over supervision of the nation's fuel oil supply within a short time, through the agency of the Federal Fuel Administration. Plans are now being prepared for the organization of an oil division of the Fuel Administration, and it will work out the scheme of control. No decision has been made as yet concerning the advisability of fixing prices, a step which was taken in connection with the Government control of coal contracts and coal distribution.

The situation as regards fuel oil has become acute within the past few weeks due to the heavy demands of the navies of the United States and Great Britain

## ENGINEERING

Owen Sound, Ont.—William Kennedy & Sons are making structural alterations to the steel foundry and machine shop.

**Lachine, Que.**—The Rapid Tool & Machine Co.'s plant has been destroyed by fire, the loss being estimated at $65,000.

**Toronto, Ont.**—The City Architect has issued a permit to the Bond Engineering Works for an addition to their factory at the foot of Cherry Street, to cost $8,000.

**Toronto, Ont.**—City Architect Pearse has issued a building permit to the Canadian Allis-Chalmers Co. for a $2,000 addition to their factory on Lansdowne Avenue.

**Banff, Alta.**—The Alberta Electro-Chemical Co. contemplate installing machinery for the manufacture of carbide in their plant at Kananaskis Falls.

**Hamilton, Ont.**—The cooperage department of the Steel Company of Canada on Wellington street north, was destroyed by fire recently, with a loss of $10,000.

**Gananoque, Ont.**—The hammer shop in the axle department of the plant of the Ontario Steel Products Co. here was damaged to the extent of several thousand dollars on Monday morning. The company expects to be in full operation again in about ten days, as reconstruction necessary will be undertaken immediately.

**Halifax, N.S.**—L. M. Trask of this city, who recently purchased the Milton Foundry at Yarmouth, has purchased the Bridgetown Foundry, which is located in the centre of the town near the river front. With his foundries and machine shops connected therewith, Mr. Trask expects to manufacture stoves, ships' castings, hoists and winches, and a complete line of fuel oil engines up to 200 h.p. suitable for vessels of all kinds. He will also make a specialty of traction engines.

**Toronto, Ont.**—The Bond Engineering Works, Ltd., which took over the Queen City Foundry, will build an addition to the foundry, the contract having been let to Chas. W. Wood & Son of Toronto. The building is to be single storey, with monitor solid brick walls, roof of standard slow-burning construction. Despite unfavorable weather the work is progressing rapidly. The Bond Engineering Works is a subsidiary of the well-known transmission manufacturers, the Bond Foundry & Machine Co., Mannheim, Pa.

**Toronto, Ont.**—The contract for building of a stave pipe line through Niagara Park, which will carry a third water supply for the development of hydro-electric power at Niagara, while the Chippawa work is under construction, has been let to the Pacific Coast Wood-Stave Pipe Co. The same concern installed a pipe line at Eugenia Falls for the Commission. When the new generator is installed at the Ontario Power Co's. plant it will give the Hydro-Electric Commission an additional 50,000 h.p. It is estimated that the pipe line and equipment will cost about $1,800,000. The work will be completed by Nov. 1.

## ELECTRICAL

**Thorold, Ont.**—The Hydro-Electric by-law was carried here at the recent municipal elections.

**Stratford, Ont.**—Owing to the shortage of power the local commission has issued an order to cut down consumption. Power for the factories will not be switched on until 8 a.m. and will be turned off at 5 p.m. each day. This means that factories which are now running from 7 a.m. to 6 p.m. will lose two hours daily.

## GENERAL

**Lindsay, Ont.**—The Allen & Hanburys Co., will build a factory here to cost about $100,000.

**Brantford, Ont.**—The flour mill at Norwich, owned by T. L. Wood was totally destroyed on Sunday morning.

**Montreal, Que.**—One of the buildings of the Montreal abattoirs, Delorimier avenue, was recently damaged by fire.

**Baden, Ont.**—The large woollen mills of Elias A. Brudacher were destroyed by fire here on Jan. 9, the building and contents being entirely burned. The cause of the fire is unknown.

**Brantford, Ont.**—When fire broke out in the three-storey plant of the Watson Manufacturing Co. here on Jan. 8, the sprinkler system held the blaze under control until the arrival of the Central Fire Department. The building itself suffered little, but the damage done to the machinery will involve considerable loss.

**Montreal, Que.**—The Arena, which was destroyed by fire recently, will not be rebuilt until after the war, so President Ed. Sheppard of the Arena Co. announced. The company owns the land on which the Arena stood, and will hold it. The ice plant adjoining the Arena was little damaged, and will be running again shortly.

## MUNICIPAL

**Lethbridge, Alta.**—The City Council propose installing additional power plant equipment.

**Owen Sound, Ont.**—The by-law to guarantee $39,000 bonds of the King Shoe Co. was carried by 51 over necessary two-thirds.

**Forest, Ont.**—The by-law to sanction the purchase of a fire engine and other apparatus at a cost of $8,500 was carried by a small majority.

**Tillsonburg, Ont.**—At the recent elections, the by-law to grant a fixed assessment of $25,000 to the Maple Leaf Harvest Tool Co. was carried by 312 majority.

**Galt, Ont.**—The by-laws for the amalgamation of the Hydro and waterworks departments and for extensions to the water works system carried by large majorities.

**Belleville, Ont.**—The by-law to grant $28,000 for the purchase of a site for the proposed new Albert College building was carried, the vote being 748 for and 242 against.

**Windsor, Ont.**—At the recent municipal elections the by-law to spend $17,000 for the erection of a municipal garage was defeated, 1,288 votes being cast against it, and only 404 in favor of the scheme.

**Swift Current, Sask.**—The work of preparation for installing the new power plant machinery is progressing in a satisfactory manner. Some of the equipment has already arrived and the erection work will begin shortly.

**Windsor, Ont.**—The ratepayers have voted in favor of the city taking over the street railway system and having it operated by the Hydro-Electrical Commission. The by-law in favor of the city building trackage was also carried.

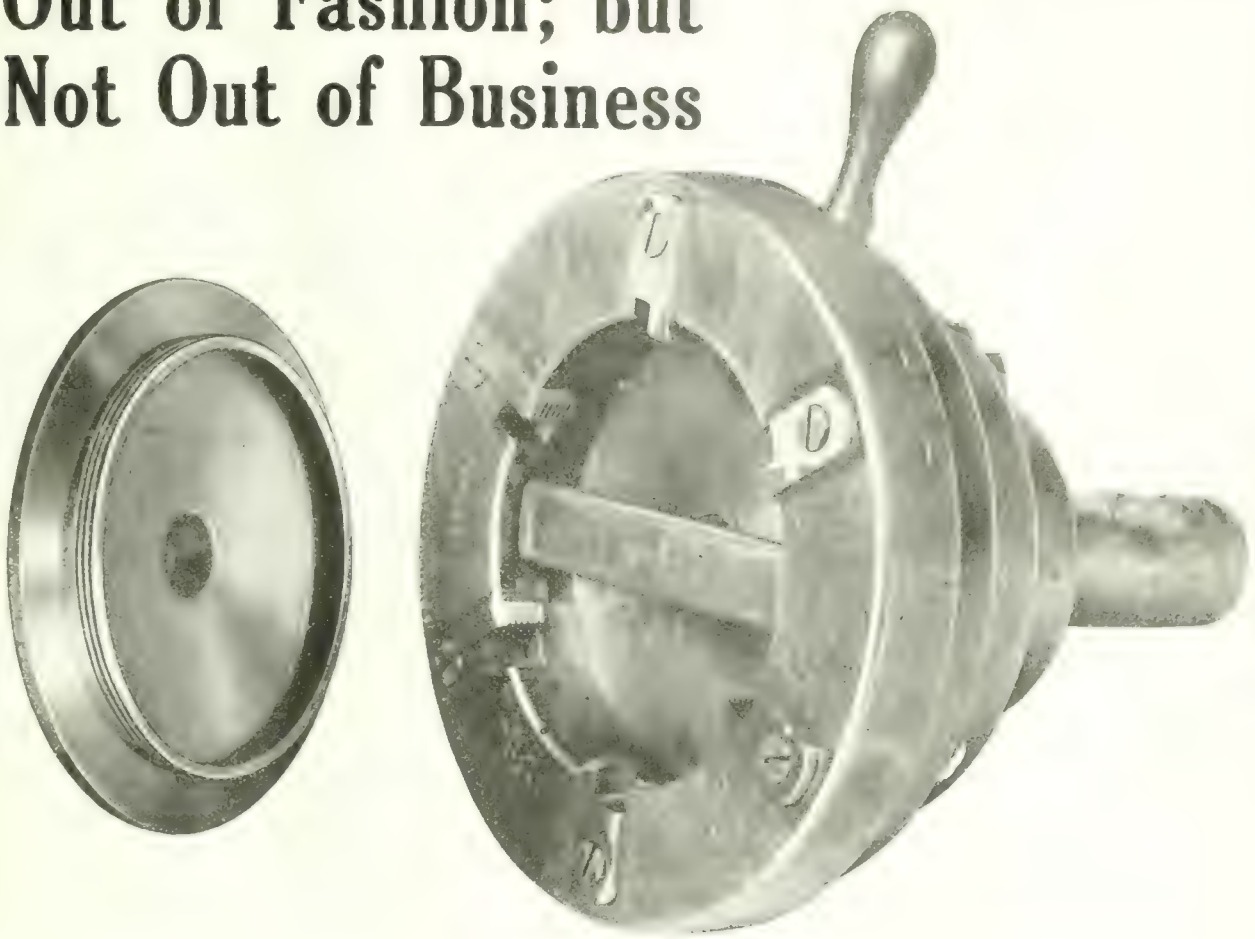
## PERSONAL

**Lieut. Harry C. Walkem, M.C.,** son of J. B. Walkem, K.C., of Kingston, has been retired from the Royal Engineers and appointed by the War Office in charge of steel contracts.

**Frank Wilton Baillie,** president of the Canadian Aeroplanes, Ltd., Toronto, and a director of the Aviation Department of the Imperial Munitions Board, has been created a Knight Commander of the Order of the British Empire.

**George A. Morrow** of Toronto has been named as an Officer of the Order of the British Empire, in recognition of his services as a member of the Aviation Department of the Imperial Munitions Board.

# Out of Fashion; but Not Out of Business



This old "war horse" of a Geometric Die Head has been cutting Screw Threads for a Chicago concern for seventeen years. It was recently sent back to the Geometric Factory for overhauling, and has gone again to Chicago, for possibly seventeen years more of duty.

A Geometric Collapsing Tap, purchased by the same people seventeen years ago, is still cutting the inside threads to match. Can you match that?

Geometric Thread Cutting Tools of to-day can surpass it. What thread cutting method are you using? Learn the Geometric way. It is a path others have trod for the past twenty-five years. Geometric experience has smoothed the path of thread cutting for many. What will you let it do for you?

*We could help you by us.*

## THE GEOMETRIC TOOL COMPANY

NEW HAVEN, CONNECTICUT, U.S.A.

*Canadian Agents:* WILLIAMS & WILSON, LIMITED, MONTREAL. THE A. R. WILLIAMS MACHINERY COMPANY, LIMITED, TORONTO, WINNIPEG AND ST. JOHN, N.B.

*If interested, tear out this page and keep with letters to be answered.*

Bertrand C. Root, [illegible] shell manufacturers expect to erect in the United States.

W. B. Fortune, one of the engineers in charge of construction of the Quebec [illegible] can International Corporation to an important position in connection with ship construction at the yard at Philadelphia, Pa.

F. F. Backus, general manager of the Toronto, Hamilton & Buffalo Railway, with headquarters at Hamilton, has been appointed railway traffic expert in charge of traffic at the Canadian terminals on the Niagara frontier. The position has been created by the Canadian Railway War Board for the purpose of supervising and expediting freight traffic from the United States.

H. C. Opie, sales agent for the Arthur Balfour Co., Ltd., of Montreal, has been on a six weeks' trip through the Eastern Provinces, and while on this trip had the memorable experience of being one of those who survived the terrible disaster at Halifax. While sitting quietly in a room at the hotel, Mr. Opie suddenly found himself blown through [illegible] which the door had just been torn. Before leaving the stricken city Mr. Opie aided in the relief work for some time after the accident.

Joseph Burr Tyrrell, B.M.A., B.Sc., F.G.S., mining engineer, of 14 Walmer road, Toronto, has been awarded the Murcheson Medal by the Geological Society of London. Mr. Tyrrell, who is one of Canada's foremost geologists, explorers and mining engineers, is at present in England. He is one of Toronto's prominent explorers, of whom little is known. He has spent many years in exploration work in Alaska and Hudson's Bay with wonderful results. The Murcheson Medal was founded in memory of Sir Robert Impey Murcheson, a famous British geologist, who died in 1871.

T. A. M. Taylor, manager of the small tools department at the Toronto branch of the Canadian Fairbanks-Morse Co., has resigned from this position and has opened an office at 318 Stair Building, Toronto, where he will engage in the small tools and machine shop supplies business. Mr. Taylor will carry a general line of supplies, milling cutters, drills, reamers, shell tools, mechanical tools, etc. Mr. Taylor joined the staff of the Canadian Fairbanks-Morse Co. [illegible] at the Montreal office and two years in Toronto. He has had charge of the small tool department for eight years, and more recently has specialized in [illegible] rooms.

# TRADE GOSSIP

D. [illegible] Mineral Production.—Revised [illegible] of the mineral production of British Columbia for 1917 show the total will be approximately $37,500,000. This is a falling off from the total of 1916 of $4,790,000.

The Canadian Steel Foundries, Ltd., Montreal have recently recieved a large order from the Imperial Munitions Board for stern frame castings for a number of vessels now being constructed in different parts of the Dominion.

Close Down on Public Works.—To conserve finances for the war, Hon. F. B. Carvell will practically close down all Federal public works. In addition to saving the money required for these works, the labor employed will be diverted to essential industries .

U.S. Steel Corp. Unfilled Tonnage.—The unfilled orders on the books of the United States Steel Corporation on Dec. 31 amounted to 9,381,718 tons, an increase of 484,616 tons compared with the orders on Nov. 30, according to the monthly report issued last Thursday.

The Frick Co., Waynesboro, Pa., have recently sold the following equipment to the Lennoxville School, Lennoxville, Que.: One 3-ton V. S. A. enclosed type belt driven refrigerating machine with high side and D. E. piping for storage rooms. To be used in refrigerator room.

The Standard Machinery & Supplies Co. of Montreal are now representing the F. B. Stevens Co. of Detroit, Mich., manufacturers of foundry facings and supplies, etc. The company will handle the complete line of Stevens products throughout Canada, with the exception of Ontario.

Trains Crossing Quebec Bridge.—Regular passenger train traffic over the new Quebec brige has been inaugurated. The service was opened Jan. 6 when a train from Moncton used this route. Hereafter trains will leave the Union Station in Quebec City daily for Montreal and eastern points via the bridge.

Armstrong-Whitworth of Canada, Ltd., have closed their office in the Dominion Bank Building and opened a warehouse at 130 Wellington Street, Toronto, in charge of J. L. Hynes, where they will carry a complete stock of high-speed steel, carbon tool steel, gauges, shop tools and special munition tools.

Ottawa Hydro-Electric.—The Ottawa Hydro-Electric Commission has had another successful year. The increase in revenue for 1917 over 1916 shows the total revenue for the first year of the municipal plant $35,000 in 1916. The expenditure showed only $16,000 increase and of this amount $12,000 was for power.

Big Lake Fleet for Ocean Service.—The United States Shipping Board has decided to remove from the Great Lakes an additional thirty ships for ocean service. The vessels will be cut in half this winter and will be removed through the Welland Canal and reassembled when navigation is resumed in the spring. Already 42 ships have been brought out.

The Standard Machinery & Supplies Co. of Montreal have been appointed sales agents for the Atlas Crucible Steel Co. of Dunkirk, N.Y. They will handle the various lines of high-speed and carbon steels in the whole of Canada, with the exception of a part of Ontario. In Ontario the territory includes Renfrew, Pembroke and east of those points.

The Liquid Air Society will in the course of a couple of months move their head office to Toronto. For the past several years the administration of the Canadian business has been done from the Montreal office; the factory at Montreal will still be maintained as a branch, and will continue to be the main production unit of the company's several branches..

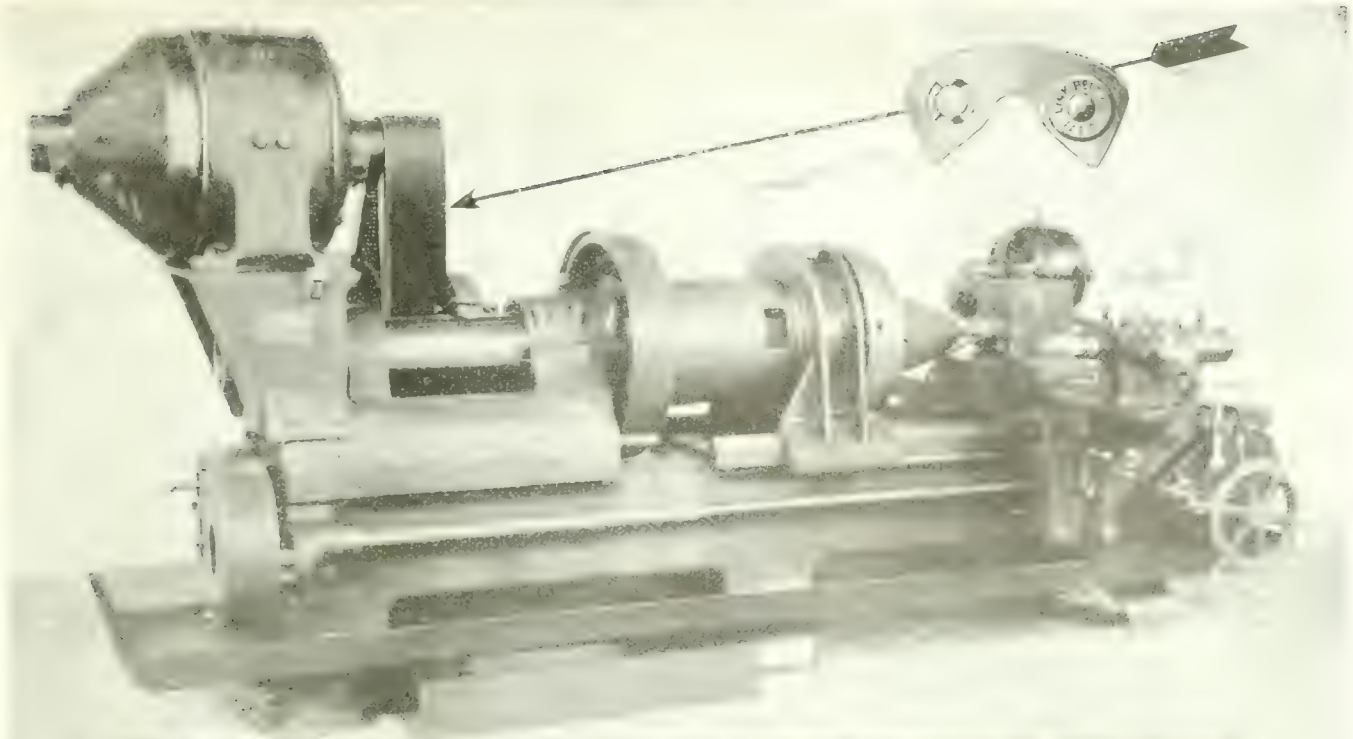
New Railway Rates in February. It is understood that the increase of fifteen per cent. in freight and passenger rates on all Canadian railways will become effective on Feb. 1. Mileage rates thus advance from 3 to 3.45 cents. The new rates have already been affirmed by the Dominion Railway Commission, and only the detailed schedules of the various lines have yet to be passed upon by the Government officials.

S. S. Angouleme Wrecked.—The steel freighter Angouleme which was built at the Thor Iron Works, Toronto, last summer is reported a wreck off the Scarlet Island on the Nova Scotia coast. The Angouleme was christened "Orleans" and was built for the Playfair interests but was later renamed and sold to the Overland Navigation Co. The vessel was 261 feet long, 43 feet wide, 28 feet deep and had a deadweight capacity of 4,500 tons.

Would Make St. John a Dominion Port.—A proposal for the Dominion Government to take over the port of St. John, N.B., make it a Dominion property, and place it under a commission similar to the Harbor Commission at Montreal, has been considered by some of the members of the Dominion Government. Hon. F. B. Carvell is taking the matter up with the Dominion Cabinet, and while it may take some time to complete the negotiations, it looks as if something may come of it.

High Speed Steel Prices Fixed in U.S.—The committee on steel and steel products of the American Iron and Steel Institute has recommended the following fixed prices on high speed tool steel. Mill shipments $2, and shipments from makers' warehouse stocks $2.01 base per pound. All prices f.o.b. point of shipment and net without discount. Tungsten finishing steel 65c per lb., on mill shipments and 66c on shipment from warehouse stocks. A long list of extras has also been submitted.

Committee to Consider Railway Problem.—To consider the whole Canadian railway problem rendered imperative by the freight rate decision, a committee composed of Hon. Messrs. Reid, Meighen, Calder, Carvell, Robertson and Sir Thomas White, has been appointed. The freight rates decision of the Railway Commission will not be given effect to until investigation by this committee. It



# THE IDEAL DRIVE

## FOR MACHINE TOOLS

MACHINE tools driven through Link-Belt Silent Chain receive all the power of the motor. Every variation of speed, every reversal, is instantaneous. Motor and headstock are linked by unyielding, yet flexible steel, permitting no slip and no backlash.

## LINK-BELT SILENT CHAIN DRIVES

lead in machine tool drives. Designers prefer them for their compactness and convenience of application. The transmission is 98.2 per cent. efficient on actual test—"Flexible as a Belt Positive as a Gear More Efficient than Either."

Write for Data Book No. 125, which tells all about Silent Chain Drives. With its assistance you can figure your own machine tool drives, and determine their cost.

is possible a further step toward nationalization of the transportation system may result.

**Western Traffic Conditions Much Improved.**—In Western Canada the action taken by the Canadian Railway War Board to increase the movement of coal from the mines to the prairie cities and towns, it was said, has had the effect of greatly diminishing the shortages which were reported a few weeks ago. On one of the lines which it was claimed should have moved more coal there has been an increase in the movement of no less than seventy per cent., and a number of the mine operators have advised that they are now receiving good service from the railways.

**Box Cars to be Returned From U.S.**—As a result of representations made by the Canadian Railway War Board to the American railway authorities at Washington, the United States railways have been ordered to send nearly 6,000 empty box cars to Canada, and deliveries of these cars will be accomplished as speedily as the lines to the south can move them out of the congested district. With these cars available, the Canadian railways will be in a position to move a great deal of the freight which has been delayed in Canada awaiting cars to move it to the United States.

**Steel Concern Changes Name.**—An interesting development in the steel trade of recent date has been the absorption of the well known Sheffield concern the Eagle & Globe Steel Co. by Arthur Balfour & Co., Dannemora Steel Works Sheffield, England. In future all Canadian business will be carried on under the name of Arthur Balfour & Co., and no change will be made in the Canadian offices, except in the name as stated above. W. A. Bradbury, 123 Craig St. W,. Montreal will continue as general Canadian agent.

**Marine Engineers Meet.**—New wage schedules showing increases were considered by the Great Lakes Executive of the National Association of Marine Engineers, who were in conference in Toronto a few days ago. The new schedule has not yet been issued, but it is understood that it will approximately be from $1,440 to $2,100 a year for chief engineers, and from $1,152 to $1,800 a year for second engineers. The present wage scale is as follows: $960 to $1,500 a year for second engineers, and $1,200 to $1,800 a year for chief engineers.

**Asbestos in Queensland.**—The restrictions on shipping and imports generally are doing much to encourage Australian enterprise. In the past Australia has been content to get supplies of asbestos from Italy, Canada, and South Africa, although promising asbestos deposits have been known to exist in Central Queensland, deposits capable of yielding unlimited quantities. Now the attention of the State Mines Department has been directed toward this natural wealth, and it is hoped that the foundation of a new industry will be firmly laid.

**Will Devise Means of Holding Dye Market.**—Manufacturers of dyes from several Canadian cities and from New Jersey, Philadephia, Chicago and Cincinnati will meet with representatives of the United States Government in New York on January 22 and 23, for the purpose of devising means of holding their domestic and foreign markets against the onslaught of German commerce "shock battalions" after the war. Formation of an International Trade Association to stabilize and standardize the dye industry, the present investment of which, it is stated, is $200,000,000, will be considered.

**Niagara Power Shortage.**—The American Cyanamid Co., of Niagara Falls, Ont., which makes ammonia for use in the manufacture of high explosives, recently reported it was 15,000 h.p. short of its usual power supply, and has been compelled to cut down its capacity very considerably. The Union Carbide Co. and the Electric Metals Ltd., two Welland concerns making war supplies, are each short about 15,000 h.p. also. In this city, St. Catharines and other places in the district, verandah lights and ornamental lights have been ordered cut off and the street lighting will be cut off after midnight soon.

**Railway Board Seeks Transfer of Tracks.**—In order to secure the rails required to keep the main arteries of traffic in good condition, it was decided at a meeting of the Canadian Railway War Board, held in Montreal recently, to petition the Government to take up the metal on lines that are not vital. This work will entail the removal of 1,500 to 2,000 miles of rails, and the Government will be asked to hold over certain classes of labor continually passing through Canada to Europe to handle it. Some 20,000 laborers will be wanted, and their wages, about $50,000 a day, will be spent in this country.

**U.S. Steel Production Cut in Half.**—It is estimated that the average steel production of the United States to-day is but little over 50 per cent. capacity. Operations at 50 per cent. capacity mean a loss of some 1,750,000 tons of steel monthly as long as the present situation continues unrelieved. And steel men can see little prospect of an early betterment. In some quarters it is thought that labor is responsible to some extent for the present tie-up of industry. Owing to the demand for workers it is claimed that laborers have assumed an independent attitude and are working carelessly and producing considerably below their ability.

**Coal Deposits Near Prince Rupert.**—The British Columbia-Skeena Coal Co. controls 30,000 acres of anthracite coal lands on the Upper Skeena River, northwest of Prince Rupert, B.C., where recent discoveries report the existence of large deposits of coal closely resembling in analysis the smokeless coals of Pennsylvania and Wales, now used by the United States and British navies, and said to be the only lumpy anthracite coal in Canada. The national importance of this find at the present time, when naval supremacy is so vital, and good coal so scarce, will be readily appreciated. Heretofore Canada's coal supply has been altogether bituminous.

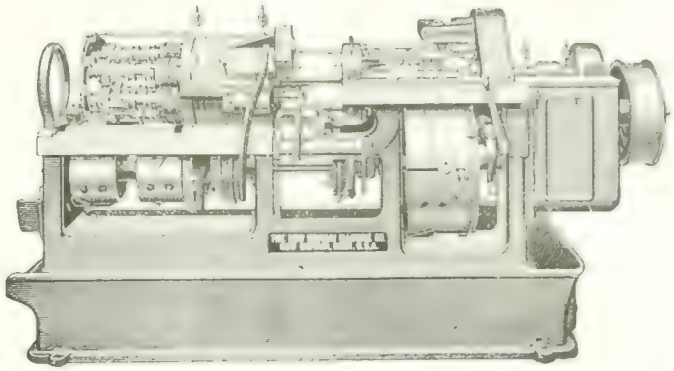
**Petroleum Production in U.S.** — Petroleum produced and marketed in the United States in 1917 reached the record-breaking total of 341,800,000 barrels, the geological survey announces in its preliminary yearly estimate. The quantity exceeded by 14 per cent. the 1916 record production. Record levels were reached and firmly maintained by prices of crude oil at the wells and the enormous demand absorbed not only the current output but necessitated a net draft of about 21,000,000 barrels of oil in storage, principally in California and Illinois. The surface reserve of crude oil at the end of the year is estimated at 153,000,000 barrels.

**Steel Men Interview Munitions Board.** —Representatives of the steel companies were in consultation at Ottawa last Thursday with the Imperial Munitions Board. It is understood the steel manufacturers object to the inspection results and would change the present system. At present the British Government employs an inspection company to pass upon the output of the munition manufacturers and of the steel for munitions. The rejections have been of so great a percentage as to alarm the producers, who allege that unskilled men are being used as inspectors. It is improbable there will be any change in the inspection system.

**Pig Iron Statistics.** — December pig iron statistics show the sharp cutting down of production in the United States in the second half of the month, and the January showing will doubtless be worse. The total of coke and anthracite iron last month was 2,882,919 tons, or 92,997 tons a day, as against 3,205,794 tons in November, or 106,859 tons a day. Capacity active January 1st was only 93,500 tons a day, as against 106,953 tons for December 1st, and only 324 furnaces were in blast January 1st, a loss of 24 in the month. December production of 2,882,919 tons compares with 3,178,647 tons in December, 1916, and 3,203,322 tons in December, 1915.

**Lifting Embargo Helps Molybdenum Industry.**—The lifting of the embargo on molybdenum, and tungsten, their ores and concentrates, is expected to have an immediate stimulating effect on molybdenum mining endeavor in that in such a broadened market inducement is offered for the employment of foreign capital, especially from the United States. Whereas heretofore the molybdenum mine operators have had their product confined to a very narrow market, securing for their output perhaps the smallest price of any of the allied countries, they will now be able to consign their product to the most remunerative markets, thus resulting in an increase of perhaps 100 per cent. or more to their income. The chief molybdenum deposits are located in Northern Ontario and Northern Quebec, the latter along the Transcontinental railway.

**Manufacturers Fear Pig Iron Shortage.**—The deputation of Ontario manufacturers who waited on the Dominion Government a few days ago at Ottawa



# Screw Machine Queries:

***"HOW IS ALIGNMENT MAINTAINED?"***

ACCURACY of *initial* spindle alignment on an automatic is taken for granted. The questions that interest a prospective buyer are: "How long will that alignment last?" and "Is provision made for taking up the slight wear that is ultimately bound to take place without disturbance of alignment?"

These two questions meet with favorable answer in the "New Britain" Six Spindle Automatic.

The use of chrome-nickel steel spindles, hardened and ground, running in *straight* bronze bearings, insures a minimum of wear, tool pressure being taken by ball thrust bearings.

The bronze bearings are taper ground outside, shimmed and fitted with nuts for maintaining a perfect running adjustment.

*Don't install another automatic until you have fully investigated the New Britain's capacity for increasing your production*

Normac Machine Co.

55 Vine Street, St. Catharines, Ont.

asking the creation of a war board to control essential war material, expressed a fear that an adequate supply of pig iron might not be available in the near future. They would have the war board empowered to negotiate with the United States for a supply. Already the government has a controller of metals, who is doing this. It is claimed that there are ample facilities in Canada for the production of an adequate supply of pig iron. The only danger is in the failure of the coke supply for the pig iron smelters. The smelters in Ontario are dependent upon the United States coke ovens for their supply, and even in the United States some ovens are banked owing to the scarcity of the necessary fuel.

**New Shipbuilding Plant at Toronto.**—Work is now proceeding on the contruction of a two-million-dollar shipbuilding plant at Toronto on the west side of the harbor. The plant is being erected for the Dominion Shipbuilding Co., which was recently granted a provincial charter. It is expected that the entire plant will be finished by next summer, when work will commence on the construction of five steel freighters for salt water service. The vice-president and general manager is L. Dahlgren of Toronto. The company has leased for a term of 21 years slightly over 15 acres of reclaimed land at the foot of Spadina avenue. They are erecting a modern shipbuilding plant, the largest building being about 800 feet by 100 feet. Five shipbuilding berths capable of taking ships of canal size, that is, up to 261 feet in length by 43 feet beam, are being erected.

**Bituminous Coal Production in 1917.**—The 1917 bituminous coal production in the United States is put at 544,000,000 tons, an increase of 42,000,000 over 1916, in preliminary estimates to-day by the Geological Survey. Fuel Administration officials had expected the total to be more than 550,000,000 tons, but a falling off in output in December reduced the figures. December's production was the smallest of any month since last April, due principally to car shortage. The last week of the month showed great improvement over previous weeks, but in that week the mines were operated at only 88 per cent. of their total capacity.

**Nova Scotia Industrial Production.**—It has been estimated that in 1917 the following values were produced by the industries of Nova Scotia:

| | |
|---|---|
| Coal | $23,600,000 |
| Coke and by-products | 5,000,000 |
| Gold and other minerals | 250,000 |
| Gypsum, limestone, etc. | 1,250,000 |
| Building materials and clay products | 450,000 |
| Iron and steel products | 20,000,000 |
| Fisheries | 10,092,000 |
| Manufactures, ships and freights | 47,750,000 |
| Products of the farm | 36,117,203 |
| Products of the forest | 4,500,000 |
| Game and furs | 500,000 |
| Total | $149,509,203 |

# WOODWORKING

**Peterboro, Ont.**—On Jan. 6, fire destroyed the factory of the Peterboro Canoe Co. For some months past the company has been manufacturing shell boxes, and the plant was stocked with machinery and materials used in this line of manufacture, in addition to the regular equipment for manufacturing canoes and power boats. The entire plant, with the exception of a warehouse, was badly gutted. The exact cause of the fire is not known. The loss to the building will be in the neighborhood of $30,000, and the machinery and stock will run the total loss considerably higher.

# INCORPORATIONS

**Modern Paper Box Co.** has been incorporated at Ottawa with a capital of $100,000 to manufacture boxes and pulp products of all kinds at Guelph, Ont. The incorporators are J. P. Hale, W. L. Clark and W. R. Mackenzie, all of Guelph, Ont.

**St. Lawrence Shipbuilding & Steel Co.** has been incorporated at Ottawa to build and operate ships, docks, etc., at Sorel, Que., with a capital stock of $1,000,000. The incorporators are P. Bercovitch, E. Lafontaine and N. Gordon, all of Quebec.

**Structural Steel Co.** has been incorporated at Ottawa by W. R. L. Shanks, F. G. Bush and H. W. Jackson, all of Montreal, to build bridges and structural work of all kinds. The company is capitalized at $5,000 and the chief place of business is at Montreal.

**The Dominion Metallurgical Co.** has been incorporated at Ottawa with a capital of $250,000 to manufacture iron, steel, alloys of all kinds. The chief place of business is Toronto, and the incorporators are H. A. Harrison, W. M. Cox and W. N. Robertson, all of Toronto.

**Pyrene Mfg. Co., of Canada, Ltd.,** has been incorporated at Ottawa with a capital of $100,000 to manufacture "Pyrene" fire extinguishers and fire fighting appliances of all kinds. The head office is at Montreal, and the incorporators are J. A. Miller, A. H. Elder and M. C. Lalonde, all of Montreal.

**The International Ore Corporation** has been incorporated at Ottawa by H. A. Harrison, W. M. Cox and W. N. Robertson, all of Toronto, to carry on the business of mining, washing, concentrating and smelting ores of all kinds. The chief place of business is at Toronto, and the capital stock of the concern is $1,000,000.

# RAILWAYS

**Guelph, Ont.**—Owing to the shortage of power the street car service here has been greatly curtailed. Manager Heeg stated recently that the situation had practically come to a question of closing down some of the smaller factories in order that the manufacture of munitions and the completion of war orders might proceed without interruption.

## BUILDINGS

**Toronto, Ont.**—The Graham Co., Chicago, Ill., are preparing plans for mail order warehouse, estimated to cost $1,000,000, for the T. Eaton Co. Toronto Office, H. J. White, 408 Ryrie Building.

## CONTRACTS

**Palmerston, Ont.**—At the recent municipal elections the by-law for partial tax exemption of the Paget Grain Door Co. passed.

**Toronto, Ont.**—The John V. Gray Construction Co. have been awarded a contract for a new boiler-house by the Swift Canadian Co.

**Brantford, Ont.**—The Austin Company, Cleveland, Ohio, have the general contract for an extension to the Dominion Steel Products plant.

## MARINE

**Toronto, Ont.**—The Toronto Ferry Co's. docks at the foot of Bay street have been destroyed by fire entailing a loss of $35,000. The steamer Chippewa was damaged to the extent of $1,000.

**Yarrows, Ltd., of Esquimalt, B.C.,** has a contract with the Imperial Munitions Board for producing thirty propellers. A large number of propellor contracts have been given to Yarrows. Each propellor has a diameter of 14 ft. 6in., and weighs roughly six and three-quarter tons.

**Chatham, Ont.**—The Chatham, Wallaceburg and Lake Erie Railway was operated last Friday for the first time with the use of hydro-electric power. For some time the road has been practically tied up, as a result of the low gas pressure, which is used to generate the current for the road. So successful was the test that it is quite likely the road will

**Vancouver, B.C.**—The wooden steamship Warnootaka was launched at the Western Canada Shipyards here last Friday. Mrs. R. A. Mann, wife of the president of the company, broke the bottle of wine over the vessel's bows The Warnootaka, named after the first white settlement in British Columbia, is said to be the first vessel of any size ever launched in False Creek. Her keel was laid July 20 last. She is 250 feet long, with a deadweight capacity of 2,800 tons.

## CATALOGUES

The Port Hope File Mfg. Co. of Port Hope, Ont., have issued a wall calendar featuring the P. H. and Imperial brands of files.

The Cleveland Twist Drill Co., Cleveland, Ohio, have issued an attractive wall calendar for 1918, which besides being of advertising value, serves to bring out a message which does not receive the attention that its importance merits. The calendar points out the invaluable work that is being done by the machinist in the great effort now being put forth in the production of munitions and equipment for the fighting forces. A copy of this calendar will be gladly sent to anyone interested.

## AGENTS WANTED

WANTED LIVE REPRESENTATIVE TO handle good specialty; one who hasn't too many irons in the fire. Apply Box 348, Canadian Machinery, stating lines you now represent and the ground you are prepared to cover. c23m

## SPECIAL MACHINERY

H. C. THOMAS, GENERAL MACHINE SHOP, tools, jigs and machine repairs. 301 King St. W., Toronto. Telephone Adelaide 3836. tf

MANUFACTURERS—WE CAN UNDERTAKE work to any specification munition production equipment or otherwise. Write W. H. Sumbling Machinery Co., 7 St. Mary St., Toronto.

## FOR SALE

One new 6" Globe Engineering Co. shell cutting-off machine. This machine is of very rugged construction, and is absolutely new, having not had a belt on it. The reason it is for sale is that since purchasing this machine we have discontinued 6" work. Address communications to Box 370, Canadian Machinery. (c4m)

## SITUATIONS WANTED

GENERAL SUPERINTENDENT, WITH PRACtical shop as well as efficient production experience, desires change. One having considerable munition experience, principally shells of various sizes. Box 358, Canadian Machinery. (c25m)

EXPERIENCED METAL PATTERN MAKER desires change. Experienced on lathe and bench and match plates; good on tool and machine work. Box 362, Canadian Machinery. (c1m)

## FOR SALE

1—3 x 26 BROWN & SHARPE SPUR GEAR cutter, splendid shape, with countershaft and arbors. Box 365, Canadian Machinery. (c2m)

ONE PRENTICE TURNING LATHE, 16" swing, complete with gears, countershaft and clutch, for sale. Hosmer Stamping & Die Works, Ltd., 350 Sorauren Avenue, Toronto. (c4m)

EXPERIMENTAL OR TOOL ROOM LATHE built by Pratt & Whitney. Taper turning attachment, splined lead screw, full set change gears, hollow spindle and tool post adjustable to different positions; capacity 12 in. swing; countershaft gear complete. Recently overhauled. Bargain for quick sale. Apply Box 371, Canadian Machinery. (c4m)

## WANTED

WANTED—ONE NEWTON OR ESPEN-LUCAS second-hand cold cutting saw, with capacity for sawing sections up to 20" in diameter. Address Ellis O. Friedman, Inc., 82 State Street, Albany, N.Y. (c3m)

WANTED—ENGINE LATHE, 18 TO 24-INCH x 10 or 12-foot bed. Give full particulars and price. Northwestern Iron Works, Regina, Sask. (c9m)

WANTED — DESIGNS, SHOP DRAWINGS, tracings, estimates, specifications made to requirements by experienced practical engineer and designer. Any mechanical proposition carried through. Box 363, Canadian Machinery. (c6m)

WANTED — COMPLETE BOLT AND NUT machinery to manufacture sizes ¼-inch diameter and up. Advise offerings in either second-hand or new. Box 360, Canadian Machinery, Toronto. (c2m)

## PATTERNS

AT YOUR SERVICE—THE BRANTFORD PATtern Works are fully equipped to handle all kinds of pattern work, large or small. We have yet to hear the first complaint either in workmanship or price. Try us with your next order. Prompt service, expert mechanics. Brantford Pattern Works, 49 George St., Brantford. (c3m)

# Comparison of Working Costs of Principal Prime Movers--I*

By Oswald Wans

*High thermal efficiency does not necessarily imply commercial superiority. Available data are seldom complete and render difficult the justification of claims and working costs advanced by advocates of respective prime movers. The engine of lower thermal efficiency may, therefore, under certain conditions, be the sounder proposition commercially.*

THE problem of economical power is one that must repeatedly present itself to those responsible for the welfare of industrial concerns, or indeed to any one upon whom falls the onus to provide power for whatever purpose. Yet the available data are seldom complete, and are frequently misleading. The claims and working costs advanced in favor of the several prime movers are often conflicting and difficult to reconcile with fact. It is not suggested that a lack of good faith is responsible, as an analysis of such estimated costs generally reveals the fact that the explanation is to be sought in the too limited basis upon which the costs have been founded. The condition that a certain type of engine possesses an exceptionally high thermal efficiency does not necessarily establish its commercial superiority. On the contrary, an engine of lower thermal efficiency may, under favorable conditions, be a sounder proposition from the commercial standpoint, and this in practice is the ultimate criterion of the engine's worth.

Working costs based mainly upon the low rate of fuel consumption are practically useless, and although the statement may be termed obvious, nevertheless, not infrequently one finds that the capital charges are either inadequately covered or entirely ignored. One may allege, without feeling, that the advocates of internal-combustion engines have been the greatest offenders in these respects, but it must be acknowledged that nowadays the undertakings of manufacturers generally are based upon broader lines, due doubtless to the accumulated data consequent upon a more extended experience.

The object of this paper is to give data that will be of service in estimating capital expenditures and working costs, and in establishing the relative commercial value of the principal prime movers. For this purpose typical examples of the following prime movers will be considered:

Suction-gas engines and plants burning anthracite, coke, and wood refuse.

Gas engines using town gas.

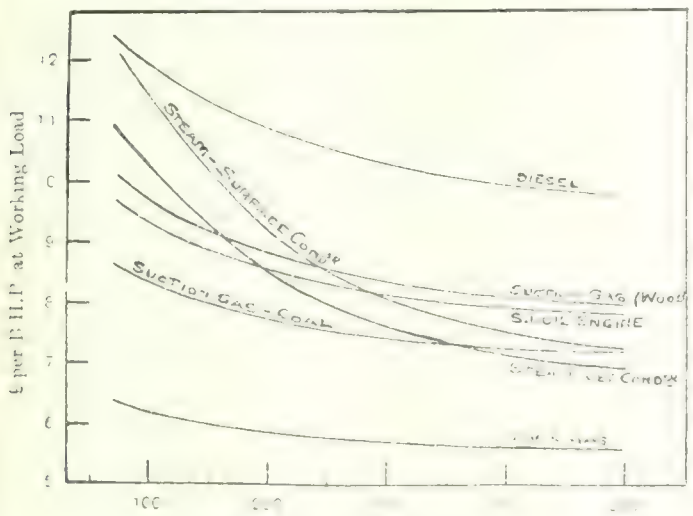
Oil engines of the solid injection high-compression type.

Diesel engines.

Steam engines.

The scope of the paper includes units up to a working load of 500 b.h.p., a power range embracing the engines for which there is by far the greatest demand. For higher powers two or more units can be used sometimes with advantage, for such installations possess a considerable power flexibility, in that the units may be cut out or put into service to suit the load requirements. This facility largely obviates the disadvantages of underloading, particularly valuable in the case of an internal-combustion engine, and offers a further advantage in the event of a break-down of one unit, for a complete stoppage of work may be prevented. In a multi-unit installation the expenditure and working costs may be taken as proportional to the number of units.

It is desirable to confine the present paper to the power units indicated, as the factors governing the costs of the larger installations are distinct, for example, the possibility of using bituminous coal with a recovery plant, live and exhaust steam turbines, etc., should be considered, thus introducing another set of conditions. It is perhaps hardly necessary to state that working costs, to be of commercial value, must contain the charges due to capital expenditure, depreciation, etc., as well as those arising from the direct running expenses. Further, the latter should be founded upon "everyday" performances; the results of



B.H.P.—Rated Working Load

FUEL CONSUMPTION CURVES

avoided.

The items constituting the total working cost are:

**Capital Charges:**
Depreciation.
Insurance.
Running Charges
" " sundry stores.
" repairs.

It is necessary to determine firstly the capital expenditure and this factor therefore will be dealt with at once and

*Read before the Institution of Mechanical Engineers, London, Oct. 19, 1917.

[illegible] investigation of the local conditions.

### Capital Expenditure

The capital expenditure should cover the total cost of the completed installation in working order. The following list gives the items included in the expenditure curves, Fig. 1.

| Installation. | Items included in Expenditure |
|---|---|
| Suction gas or Town gas engine. Solid injection oil engine. Diesel engine. | Industrial engine, pulley, foundation bolts, compressed air starter with receiver and connections, exhaust pipe and silencer, barring gear, cooling tower, tanks, water circulating pipes and pump, foundation erection. |
| Additional for suction gas engine. | Producer, cleaning plant and charging platform, air and gas piping, producer foundation and bolts, erection. |
| Additional for town gas engine. | Gas mains connections and service piping. |
| Additional for solid injection oil engine and Diesel engine. | Fuel tanks and piping. |
| Steam engine. | Industrial jet and surface condensing super-heated steam engines, barring gear, foundation and bolts, steam, exhaust and feed piping, boiler, seatings and flues, super-heater, feedwater heater and pump, steel chimney, economiser for 150 b.h.p. and upwards, erection. |

It will be observed that buildings and flooring have not been included. These exemptions are made, as their cost varies widely, being largely dependent upon the taste of the purchaser, and may, therefore, range from a bare galvanized structure to a substantial stone or brick building. Furthermore, existing buildings are frequently used with more or less modification.

quire a covering, whereas some form of protection is necessary for a boiler. A well-equipped engine-house should possess a crane, but the cost of this item is dependent to a certain extent upon the proportions of the engine-house, and has consequently not been taken into consideration, but its cost would not be materially different for the several types of engines. Cooling towers have been included in all cases, with the exception of the small gas and oil engines of about 50 b.h.p., as the more usual practice is to employ cooling tanks suitable for thermo-syphon circulation.

When deciding the size of the engine, it is necessary to consider its overload capacity, for this factor greatly affects the capital expenditure, the reliability, and the fuel economy. It may be remarked in passing that much of the trouble at times experienced with internal-combustion engines is solely due to excessive overloading. That gas and oil engines should have a large power margin is an essential of reliability and cannot be too strongly emphasized. The effect of the overload capacity upon the economy of an installation is dealt with later, and for the present merely its influence upon the capital expenditure will be examined. The maximum overload that may be depended upon varies considerably with the type of engine, thus:

Steam engine . . . 35% above rated working load
Solid injection oil engine . . . . . 15% above rated working load
Diesel engine . . . . . 15% above rated working load
Gas engine . . . . . 10% above rated working load

The larger overload carried by a steam engine is a characteristic of considerable value in the handling of fluctuating and peak loads. Moreover, this advantage is attained without impairing the fuel economy at the working load. Unfortunately this feature is not possessed by an internal-combustion engine. An overload of 35 per cent. may be carried, but only at the expense of the fuel economy at the mean working load, which in the case of a gas engine would be about 18½ per cent. below the rated working load.

The degree of importance to be attached for all installations. A common maximum load of 35 per cent. above the mean working load consequently has been assumed, and the effect upon the capital expenditure is illustrated by the following table:

| Plant. | Rated Working B.H.P. | Rated Max. B.H.P. | Necessary Inc. in Rated Max. Load to give 35% overload |
|---|---|---|---|
| Steam engine . . | 100 | 135 | Nil |
| Oil engine . . . . . | 100 | 115 | 17½ per cent. |
| Diesel engine . . . | 100 | 115 | 17½ per cent. |
| Gas engine . . . . | 100 | 110 | 23 per cent. |

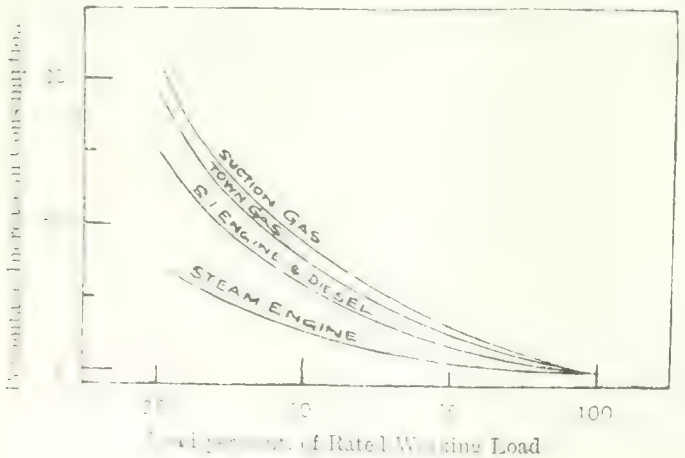
For a mean working load of 100 b.h.p. and 135 b.h.p. maximum load it will be seen from the fourth column that a larger internal-combustion engine is required than is indicated by the rated working load. For example, the gas engine must have a maximum load some 23 per cent. greater than the rated maximum load usual for a 100 b.h.p. rated working load engine requiring, it follows, a larger engine and outlay than appears at first sight to be necessary.

The expenditure curves, Fig. 1 (page 71), give the total cost per b.h.p. at the rated working load, and from which it will be seen that the cost of suction-gas engine and plant of 100 to 110 b.h.p. is £8.3×100=£830 as against £8.1×123=£997 for a 100 to 135 b.h. engine. That is to say, the cost of the gas engine is increased by approximately 20 per cent. in order that it may perform a duty equivalent to a steam engine of 100 b.h.p. rated working load. This example serves to illustrate how necessary it is when comparing capital expenditures to place the comparison on "all fours" as regards power capacity.

The expenditure curves are based upon the costs of horizontal engines, excepting Diesel engines, but would not be greatly different for the vertical type. Generally speaking, vertical engines cost more per horse-power, but a saving is effected in the cost of the foundations.

### Depreciation

A divergence of opinion appears to exist as to the annual charge that should



SUCTION AND LOAD CURVES

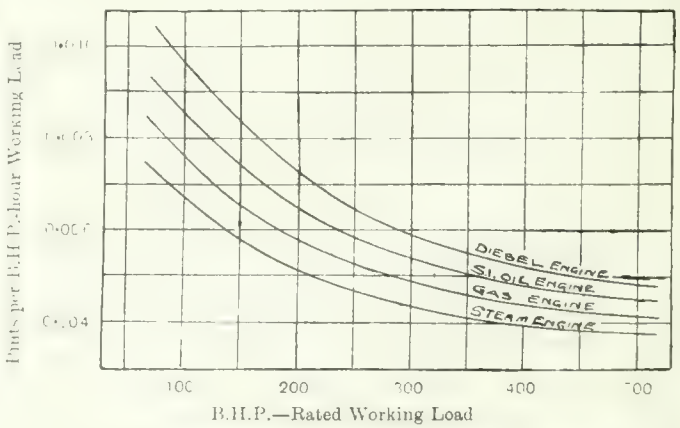


FIG. 1. LUBRICATING OIL CONSUMPTION CURVES.

The cost of the buildings for internal-combustion engines would be less than for a steam plant, and this applies equally to suction-gas engines, for the producer and cleaning plant do not re-

ed to the overhead capacity of an engine can be decided only after full consideration of the duty required, but for the purposes of comparison it is necessary that similar load conditions are consider-

be made to cover depreciation. The seller naturally wishes to place as favorable a complexion as possible upon the engine in which he is particularly interested, and it is to be feared that this

desire tends to under- rather than over-estimation of the charges under this heading. Generally speaking, the estimated costs of steam installations show a greater uniformity and liberality in this respect than is usual with internal-combustion engines. As an example of

iginally installed. Yet it is surprising how often one finds an antiquated engine struggling along with its load, and positively eating money that could be saved by substituting a modern plant. The depreciation of 5 per cent. referred to above corresponds to a life of well over fifty

especially suitable a particular type of prime mover, thus eliminating this factor and thereby deferring the probable date at which the plant may be considered obsolescent.

**Insurance and Interest**

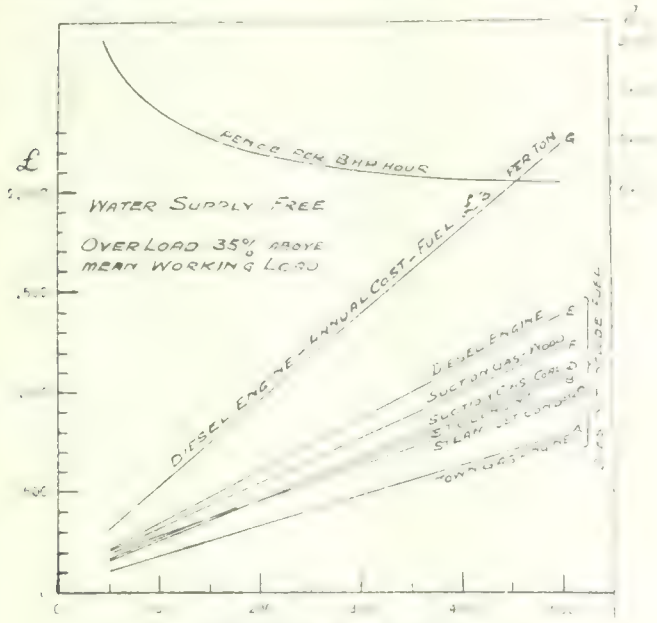

FIG. WORKING COST CURVES

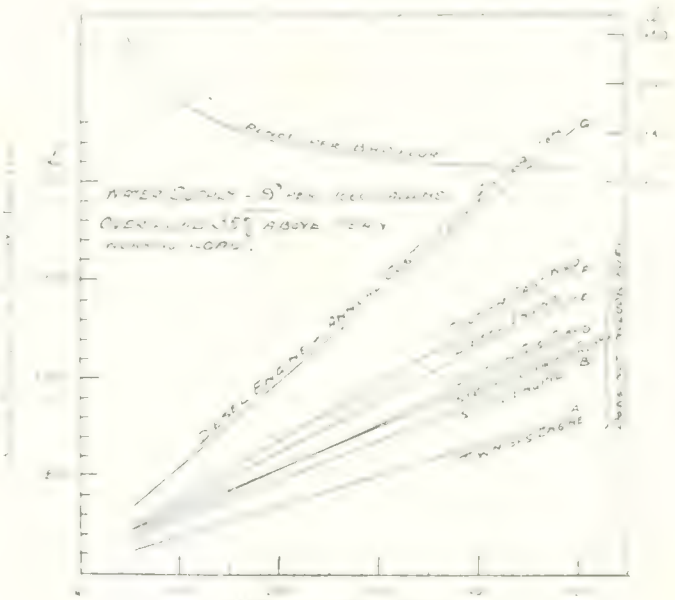

WORKING COST CURVES

the low rate for depreciation for the latter, the not uncommon charge of 5 per cent. may be cited. A little reflection should show how inadequate a provision this affords. It will be well to explain briefly what is here implied by the term depreciation. The depreciation charge is considered as the annual amount that should be written off the capital expenditure to cover the deteriorating value of the plant as regards obsolescence. This definition does not agree with general usage, inasmuch as wear and tear are not included.

In the author's opinion this departure is justified because:

(1) Developments are nowadays so rapid that there is an increasing tendency for a power plant to become economically obsolete before it is worn out.

(2) The allowance made for repairs should be sufficient, in a modern engine, to cover wear and tear during its economical life whilst serious breakages should be covered by insurance.

Viewed from these standpoints, it follows that the depreciation charge is solely dependent upon the anticipated economical life of the installation. In other words, it is not a matter of how many years an engine may run, but for what period it can be reasonably expected to maintain its economical superiority over competing prime movers irrespective of type. Immediately this superiority is lost, the commercial value of the installation, as a source of power, falls and the advisability of replacing it by an up-to-date plant should be considered.

It is false economy to keep a plant in service merely because it continues to perform the duty for which it was originally installed. Yet it is surprising how often one finds an antiquated engine struggling along with its load, and positively eating money that could be saved by substituting a modern plant. The depreciation of 5 per cent. referred to above corresponds to a life of well over fifty years, if based upon the diminished value and allowing a high scrap value or about twenty years if taken in equal annual instalments. In either case the anticipated life is obviously excessive. The determination of this period must, in the nature of things, be somewhat prophetic, nevertheless the past, to a great extent, is an index to the future, and it may be inferred that an internal-combustion engine before the expiry of twenty years' service would be an extravagant consumer of fuel, and in a generally worn-out condition; indeed, this would be equally true of a steam installation.

The depreciation rate should spread the expenditure burden over a reasonable number of years, and permit in good time of the removal of the power plant in favor of a more modern type, should the developments in later-day practice render the running costs comparatively high. It is considered that a uniform annual rate of 8 per cent., equivalent to twelve and a half years' service, fulfils these conditions, and that this rate should apply to all the prime movers under consideration, seeing that the commercial life is dependent upon the best practice, irrespective of the type of engine. The amount written off annually is, therefore, 8 per cent. of the total expenditure given by the curves, Fig. 1 (page 71).

It should be noted that this uniform rate is intended to apply to cases in which the several prime movers under consideration are applicable and, therefore, in competition. The competitive factor applies to the large majority of installations, but there may be instances in which the working conditions render especially suitable a particular type of prime mover, thus eliminating this factor and thereby deferring the probable date at which the plant may be considered obsolescent.

**Insurance and Interest**

The insurance premium for engines usually covers breakage, but not wear and tear, and this fact should not be lost sight of when fixing the annual reservation for repairs. The premiums range from about one-eighth per cent. of the cost in the case of boilers to about 3 per cent. for Diesel engines. The charges under this heading are therefore comparatively small, whereas the accruing advantages are self-evident. The rate of interest upon the capital expenditure has been taken as 5 per cent. in the working costs, curves Fig. 5 and 6.

**Cost of Fuel**

As already stated, estimated working costs, founded upon the fuel consumption possible at the most economical load, are of little value. Everyday figures only should be considered, and failure in this respect is frequently the cause of erroneous estimates. In practice the engine seldom runs at the rated working load, having to cope alternatively with loads that may be temporarily greatly in excess and at other times considerably less. These practical conditions have a marked bearing upon the working costs, and particularly so in the case of an internal combustion engine.

The accompanying curves, Fig. 2 (page 71), show the average consumptions in B.T.U. per b.h.p. hour at the rated working load. These values, however, hold good only when these loads are carried continuously, and the extent to which modification is necessary to suit practical conditions is contingent upon the load factor and the peak loads to be

ed upon its merits, but to effect a comparison a common overload of 35 per cent. will be assumed again. This condition necessitates the underloading of all the installations with the exception of the steam plant, that is to say, the mean working load will be below the rated working load to an extent dependent upon the maximum load capacity of the unit.

This unloading increases the consumption, and the curves, Fig. 3, show the average percentage increase for a given decrease in load below the rated working load.

These curves clearly indicate the importance of the correct determination of the load factor, and the absolute necessity to consider similar load conditions in order that a true comparison may be made. The following table shows the increase in full consumption due to the underloading necessitated by an overload of 35 per cent.:

| | | Increase |
|---|---|---|
| | working load | from Fig. 3 |
| Steam engine ..... | Nil | Nil |
| Oil engine ..... | 14.5 | 2.5 |
| Suction gas engine... | 18.5 | 12.0 |

A farther allowance must be made for stand-by losses, which will depend upon the frequency and length of the stoppages. This loss of course applies only to suction-gas and steam installations, and the amount may vary considerably according to the care exercised. The following values, expressed as a percentage of the fuel consumption at the rated working load for a working week of 60 hours, have been included in the working costs, curves, Fig. 5 and 6.

| | per cent. |
|---|---|
| Suction-gas installations, anthracite | 8 |
| Suction-gas installations, wood | 6 |
| Steam installations | 15 |

In cases where the plant runs continuously throughout the week, the losses would be considerably less and would be about one-third, assuming that the boiler or producer fires are kept alight over the week-end.

## BANK OFFICIALS REVIEW ONTARIO'S 1917 TRADE

IN the course of a comment on business conditions written by leading officials of the Canadian Bank of Commerce and forming part of the report of the annual meeting of that institution it is pointed out that it should be constantly borne in mind that the large measure of prosperity which the people of Ontario continue to enjoy is almost wholly attributable to the extraordinary requirements created by the war. The increasing demand for commodities of almost every description stimulated production throughout the year and unceasing activity has characterized practically every important branch of industry in the province. Agricultural returns are above the average, manufacturing results are most satisfactory, the mining output has been large and business conditions generally are sound; in fact, substantial progress has been made towards placing many industries, both old and new, on a basis which should enable them to meet successfully the keen competition for trade which is anticipated after the conclusion of peace.

### Manufacturers Prosperous

The manufacturing industries have prospered in a manner far exceeding all expectations, which is largely the result, either directly or indirectly, of the Government expenditure on supplies for the war. Manufacturers of munitions during the greater part of the year have been working to capacity, but latterly, owing to the cessation of orders for shells, fuses, etc., there has been some slackening in activity. All steel plants, rolling mills, and wire mills have been fully occupied. The manufacture of agricultural implements has received special impetus from the heavy purchases of the farmers throughout the Western provinces. Motor car manufacturers have been busy and some plants report the largest output on record. Considerable development has taken place in the production of woollen goods, and it is conjectured that the Canadian mills will be able to hold a larger share of the domestic trade after the war. Orders for munitions and military supplies have latterly been received from the United States, and it is anticipated that many mills will be fully engaged with these until midsummer next. All this increased activity has been accompanied by steadily increasing cost of materials and of labor, particularly of the former, the scarcity of which in many lines is increased by the prolongation of the war.

### Purchasing Power High

The purchasing power of the public remains high and wholesalers and retailers report business as being exceptionally good, with collections promptly made and losses from bad debts unusually small. The difficulty of securing certain lines of merchandise has increased. Owing to the check experienced as a result of the cessation of munition orders, buying has proceeded carefully and merchants realize more clearly than ever before the necessity of carrying reasonably light stocks. The labor situation caused manufacturers considerable anxiety and difficulty during the first part of the year, but this condition has been somewhat ameliorated owing to the lessening of munition orders.

There has been little movement in real estate or in building, although the demand for small houses is in excess of the supply. A fair inquiry exists for good farms, and there has been less tendency on the part of renters to leave their farms. The high price of labor operates as a deterrent to any great extension of a back-to-the-land movement, which the prevailing high prices might justify. Payments of interest and principal on mortgages have been up to the average, with little or no increase in the demand for new loans.

### Lend Surplus Funds

That the inhabitants of the Province of Ontario as a whole have enjoyed unexampled prosperity during the past few years has been signally demonstrated by their response to the appeal to lend their surplus funds and future savings to the Dominion of Canada for the carrying on of the war. The Victory Loan offered by the Minister of Finance amounted to $150,000,000 and 362,900 individual subscribers in the Province of Ontario alone applied for $203,823,500, much more than the total loan and nearly half of the amount subscribed by all the provinces of the Dominion, which amounted to about $417,000,000. This great achievement will undoubtedly result in a new spirit of thrift and economy, while the self-discipline and accumulated savings should aid materially in lightening the load which later on will have to be carried through the period of readjustment that must of necessity follow the declaration of peace.

## RAILWAY EARNINGS SHOW GOOD INCREASE

GROSS earnings of the three principal railway systems of Canada aggregated $255,552,275 in the calendar year 1917, exceeding the largest total previously recorded for any year, namely, 1916, by $21,264,805, or 9.1 per cent.

The figures for the year, as compiled from the weekly earning returns of Canadian Pacific, Grand Trunk and Canadian Northern, were completed by Canadian Northern's return for the final ten days of December. While the weekly returns are subject to slight adjustment in the final monthly reports of the companies, the comparisons from year to year vary but slightly in the grand aggregate.

The rise from the acute depression of 1914 has been spectacular in the extreme. Against some 179 millions in that year the receipts of the roads rose to 255 millions in 1917, an increase of 76 millions, or about 43 per cent. On the upward swing the previous high mark in gross business established in 1913 has been exceeded by 37 millions.

The record for the year by months shows the heaviest gains in the spring months, as compared with 1916, some narrowing of the increases in the summer and a further expansion in the autumn. The only month in which the figures fell below the 1916 level was August.

The individual returns of the companies for the year show a fairly even percentage of expansions. It may be noted that while the weekly returns place C.P.R.'s aggregate at the new high level of $148,937,000, the actual total in the monthly returns, based on complete figures for eleven months and weekly figure for December, will exceed $152,000,000.

## WORK OF SHIPPING BOARD OF GREAT MAGNITUDE

THE first annual report of the United States Shipping Board, brief mention of which was made in last week's issue, says among other things that the Emergency Fleet Corporation, which is the most important of the board's war powers, is now engaged in what is probably the greatest construction task ever attempted by a single institution. It has developed for this purpose within a period of six months an organization of more than 1,000 employes, including a large force of technical experts. The corporation has sixteen offices in various parts of the United States. It is supervising the building of 1,118 vessels in 116 shipyards distributed throughout the United States. It is disbursing for the construction of those ships something in excess of a billion dollars per annum. It is controlling substantially all the shipbuilding of the country other than of naval vessels, and its program calls for the completion in 1918 of eight times the tonnage delivered in 1916.

### Meeting the Situation Fairly

When the United States entered the war, says the report, American shipbuilders were principally engaged in the construction of ships for foreign account, principally British and Norwegian. The yards were working substantially at capacity. The problem of the corporation, therefore, was not merely to build ships, but also to build new yards in which more ships might be constructed.

To this end, contracts were placed for a large number of wooden ships, most of them to be built in new yards, it being found that such ships could be built, within certain limits, without interfering with the steel ship program. The corporation has experienced some difficulty in arranging for supplies of proper lumber, but it is believed that this difficulty has been largely overcome and that the wooden ships may be expected to be completed with a fair degree of promptness.

### 2,500 Ton Steel Ships Requisitioned

As to steel ships the corporation has made every effort to standardize designs for steel construction, but it is deemed inadvisable at this time to publish the details of those designs.

In order to speed up construction and to assure unity of control over shipyards, the corporation, on August 3, 1917, in accordance with President Wilson's order of July 11, 1917, requisitioned all steel ships under construction of over 2,500 tons dead-weight capacity. As a result of this order the United States became possessed of 413 ships in various stages of construction, of a total tonnage when completed of 2,937,808 tons. Of these, 33, of a total tonnage of 257,575, have been completed, and it is estimated that the remainder will be delivered within the next 18 months.

### Training the Workers

The corporation is making rapid progress in placing direct contracts for ship construction. In the last analysis it is man-power that builds ships; and the mobilization of a large, competent, trained and willing force of workers for the shipyards of the country has been among the most important of the corporation's activities.

Other [illegible] low:

The board has recently adopted a policy of requisitioning for government account all power-driven steel cargo vessels of 2,500 tons dead-weight or over, and all passenger vessels of 2,500 tons gross register or over, adapted to ocean service. The operation of these vessels is entrusted in large part to the companies by whom they were formerly controlled, but all receipts have been for government account, the owners being credited with the requisition rate fixed by the board. The vessels, moreover, are under full control of the board as to voyages, cargoes, and rates and as to safeguards for their protection against the hazards of war-zone service. It is hoped that this policy will be the means of achieving two results which in the opinion of the board are necessary: First, complete unity of control over the distribution of shipping, so that war needs may be filled in the order of their emergency; and second, just and effective regulation of rates, so that [illegible] war with Germany may not be financially exhausted by extortionate transportation charges.

Further experience may develop that, consistent with the purposes above outlined, some of the steamers not adapted to war service may profitably be released from requisition. As to other lines, more effective methods of regulation and control may prove to be necessary. It should be borne in mind that aside from the requisition power the board at present has no jurisdiction over rates in foreign trade and no jurisdiction over interstate rates, except where vessels are common carriers operating on regular routes. If experience shall prove it to be necessary, the board will recommend drastic legislation to meet more effectively the situation arising from the acute dearth of tonnage.

The freight rates to be charged to shippers on requisitioned vessels left in commercial service or assigned to foreign governments have been the subject of careful consideration. The board, of course, has no desire to profiteer at the expense of any government associated with the United States in the war against Germany, or of the general public. On the other hand existing contracts, particularly those on a c.i.f. basis, and special market conditions often present a danger that a reduction in rate will not insure to the benefit of the consumer but will merely transfer from the shipowners to favored shippers the monopoly earnings which it is intended to eliminate. The policy of the board therefore will be to charge freight rates based on the requisition rate whenever it can receive assurance that the benefit of these low rates will accrue to the American or allied governments or to the consuming public; and to charge higher rates whenever this fact shall not be so established. The application of this policy will no doubt present difficulties in individual cases but it is believed in principle to be sound.

The requisition program as yet has been in effect for such a short period of time that no accurate statement of receipts and expenditures can now be made. Accounts, however, are being kept with scrupulous care along sound and conservative lines, and in due season will be presented to the Congress.

### Ships From Great Lakes Utilized

The Great Lakes, shut off as they are from sea-level connection with the ocean, have nevertheless contributed materially to the work of procuring tonnage for war purposes. An unprecedented number of newly constructed ships have been brought down from the Lakes, and in addition 21 steel steamers have been withdrawn from Lake commerce and are being brought down for war service. Of these, 16 were too long to pass through the locks, and it was necessary to cut them in two, bring them down in parts, and reassemble them on the St. Lawrence. Twelve of the vessels were put together afloat, an achievement never before accomplished. Ten steel tugs have also been commandeered from the Lake fleet, and are being fitted with surface condensers for ocean use.

A committee has been appointed to advise the board as to the matter of just compensation to be paid for vessels from the Lakes to which title has been taken, [illegible] its task.

### Chartering Committee's Duties Outlined

The program of control of shipping through requisition covers only American steam vessels over 2,500 tons dead weight. To exercise a salutary degree of control over other American and neut[illegible] a chartering committee was established, with offices in New York; and with the assistance of the War Trade Board all charters of neutral ships, of American steamers under 2,500 tons, and of sailing ships of any size loading from ports of the United States to foreign ports, must be approved by this committee. The committee has exercised this control with two primary objects in mind: First, so far as possible, to induce neutral tonnage to assume its fair share of trans-Atlantic trade; and, second, to effect a material reduction in the high charter rates prevailing, not only in trans-[illegible] oriental trades.

Under Schedules 1591 and 1593 the Bureau of Supplies and Accounts of the Navy Department is calling for bids for furnishing various navy yards with large quantities of electrical material. Among [illegible] magnet wire, etc.

The War Trade Board has passed a resolution authorizing the director of the bureau of exports to license freely cargoes originating in the United Kingdom, France and Italy or their colonies.

possessions or protectorates when shipped via United States ports to United [illegible] ports, etc.

[illegible] that which leaves Canada by rail, passing through the United States in bond, and then shipped from a United States port, and cargo shipped from Canada by [illegible] at a United States port.

With regard to shipments from Canada to Japan [illegible] by steamers which call at a port of the United States, the same ruling will apply as to shipments from Canada to England, and such cargo will be licensed by the collectors of customs in exchange for copies of the manifest.

Eighty commercial automobiles, valued at $69,709, and 1,020 passenger motor cars, valued at $676,483, were exported from the United States to Canada during October, according to the latest returns of the Department of Commerce. During the ten months' period ending October, 1917, there were 696 commercial motor cars, valued at $913,088, and 14,261 passenger automobiles, valued at $10,791,081, imported into Canada from the United States. The combined exports of commercial and passenger automobiles from the United States to the Dominion in October a year ago numbered 1,021 cars, valued at $718,962, while during the ten months' period of that year they were 11,118 cars, valued at $8,025,079.

## TRAIL SMELTER OUTPUT

OPERATIONS of the Consolidated Mining and Smelting Co. of Canada, during the year ending September 30, 1917, were significant and not only was the great enterprise at Trail, B.C., a financial success, but satisfactory progress in the matter of development has been made as well.

The main achievement was the production of 10,000 tons of pure zinc of a value of $3,000,000, which event marks a definite stage in the metallurgical history of the country. The production of refined lead was increased by 2,000 tons to 22,000 tons, the production of sulphuric acid was doubled, and a new record was made by the production of $13,000,000 worth of metals.

J. J. Warren, managing director, states that a daily production of over sixty tons of pure zinc was reached during the year, and that an extraction of over 90 per cent. was made from certain classes of ore. Since the process has been standardized every effort is being made to reduce costs, and a concentrating mill with a capacity of 400 tons of ore a day is being operated to treat the Sullivan zinc ores. On the question of profits, the managing director gives [illegible] Board [illegible] tation of a keen buyer, inasmuch as the Board has required that the company meet the prices current in the United States with a certain allowance for [illegible]

has absorbed the bulk of the company's production, the Canadian commercial requirements having slackened very considerably during the war.

## AMERICAN DYE MAKERS ORGANIZE

REPRESENTATIVES of more than 200 aniline dye manufacturing firms and corporations and dealers in dye stuffs met in New York, January 22 and 23, to discuss the formation of a national trade association to serve as a clearing house for information in stabilizing and standardizing the dye trade. In the three years since January, 1915, the business of dye making in the United States, has increased with almost immeasurable rapidity until to-day there exists a commercial development in which $200,000,000 of capital has been invested, but which is without standards as to quality, production, costs, credits, exact terminology, etc.

H. Gardner McKerrow, manager of the Textile Department of E. F. Drew & Co., Inc., has taken the lead in organizing the movement for the meeting, Mr. McKerrow is spokesman for a large element in the dye trade that seeks a co-operative association which will standardize colors and tints, voice the consensus of the trade on tariff schedules, formulate contract forms, provide for the arbitration of disputes, and serve as a clearing house for the exchanges of trade information on credits, packing, labor and raw materials.

"Before the outbreak of the world war there were less than half a dozen dye manufacturing concerns in the United States contending with the competition of the incredibly efficient German aniline dye manufacturers," said Mr. McKerrow. "To-day there are more than 200 American manufacturers of intermediates and of aniline dyes and there has been invested $200,000,000. The business has been supassingly prosperous but prosperous under conditions of fictitious values and the curtailment of competition."

"The leaders in the trade are anticipating the economic stress of peace times, when the German manufacturers, striving to recover their place in American markets and in other export fields, will have the backing of their most proficient trade methods, their co-operative cartels, and the support of state mobilized shipping and banking facilities. American dye manufacturers, each with his own color standard, his own standard of concentration of dye stuffs, experimenting for himself as to specialties, etc., will be unable to withstand the teerible drive of the highly trained shock battalions of Teuton aggressiveness in the world markets.

Mr. McKerrow said that several representatives of the Federal Government from the various governmental departments interested in the production of coal tar derivatives would attend the dye manufacturers' meeting. The large Du Pont interests have expressed great interest in the meeting and will be represented. There will be representatives from dye manufacturing firms and corporations in Passaic, Paterson, Camden, Jersey City, N.J., from Cincinnati, Philadelphia, Chicago, Boston, Providence, and Toronto and Montreal, Canada.

## U.S. STEEL CORPORATION OUTPUT

THE United States Steel Corporation reports that unfilled orders on hand December 31 amounted to 9,381,718 tons, compared with 8,897,106 tons on November 30, an increase of 484,612 tons.

Unfilled tonnage on hand Oct. 31 amounted to 9,009,675 tons; on Sept. 30, 9,833,447 tons and on December 31, 1916, 11,547,286 tons.

The increase of 484,612 tons in the unfilled tonnage in December was much more favorable than looked for. Preliminary estimates had it that there would be a decrease of something like 200,000 tons. The December statement shows that new business came in at a rate almost 20,000 tons daily in excess of shipments.

The inability of the Steel Corporation to ship its products, due to inadequate transportation facilities, evidently had a great deal to do with the increase, but it is evident that new orders in December were very close to capacity. December shows the first increase in unfilled tonnage since April, 1917. Unless there is a decided change for the better in transportation facilities, the current month should show a further increase in orders, but it must be borne in mind that these increases are largely at the expense of shipments and earnings, and do not represent conditions as they actually exist, because, had normal shipments been made in December there would have been an increase in that month, but a much smaller one than actually reported.

## TOO MANY APPLICANTS FOR MUNITIONS WORK

MARK H. IRISH, director of the Department of Labor, Imperial Munitions Board, Toronto, recently issued a letter on the subject of labor. He says:—

"It has been brought to my attention, by the Ontario Government Employment Bureau, that large numbers of men and women applying for work state their preference for positions in munitions plants, and, when informed that, at the present time, there are no vacancies, continually decline opportunities in other industrial lines, stating they prefer to wait for openings in munitions production rather than bind themselves elsewhere.

"Such actions doubtless arise from a belief that an increase in munitions will shortly be needed. I am aware that there is no foundation for such opinion, and I earnestly repeat the advice that I gave last autumn, namely, where employment is desired, such employment should be secured, and under no circumstances should existing chances for work be put aside in the hope of a demand for employees from munitions plants."

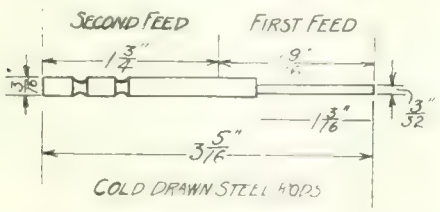
## HOW A SCREW MACHINE JOB WAS DONE

By H. Middletown

WE had to turn out a quantity of the rods shown in the drawing. They were easy to make but at the time the only machine available was a ⅜ in. Hartford automatic which was suitable for work only 1½ in. in length. That was sufficient for the portion to be turned and it was by stretching things a little increased to feed 1¾ in. The stock was then arranged to feed out 1 9/16 in. for the first operation of turning and then to



feed the remaining 1¾ in. for the necking and cutting off operations. Two stock stops were used in the turret and the box milling tool located between them to provide the proper sequence of operations. The fourth hole in the turret head was left vacant.

As is apt to be the case when working near the limit, an interference occurred and in an unexpected quarter. It was found that on bringing back the turret after the turning operation the turret would start to index before the box tool had cleared the work. This was apparently an insurmountable obstacle and held up the job a couple of days. It was finally suggested that the chuck be opened a little previous to allow the stock to be drawn back ¼ in. which was enough to clear the tool while it swung by, this to be followed by feeding up to the stop as before. This simple little trick solved the problem and the job was run [illegible]

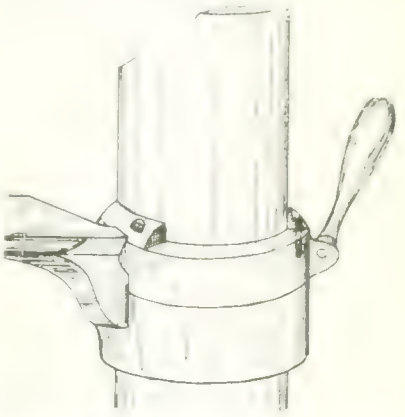
## IMPROVEMENTS TO SENSITIVE DRILLS

By Donald H. Hampson

TO anyone who has worked any length of time around sensitive drills, there must have occurred the question, "why don't the makers make certain minor improvements that would add so much to the life of the machines?" Such improvements would be a positive fastening for the rack on the back of the quill, an adjustment to take up the slack between this rack and its pinion, a dirt protector for the table where it slides on the column, and a better fastening than a set screw for the head or socket that contains the hand feed rod.

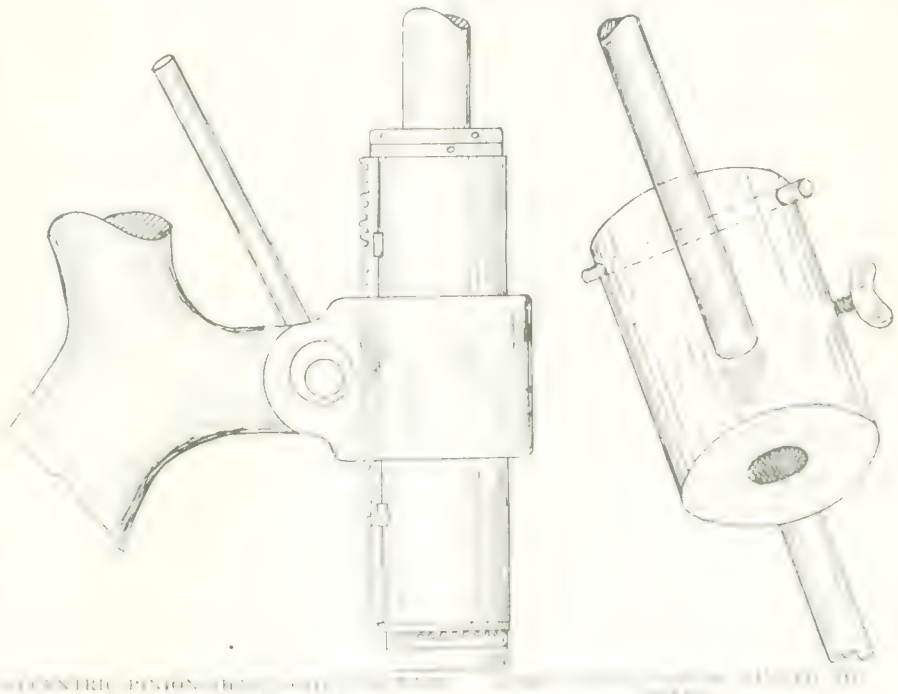
The first two defects are felt most keenly when counterboring or drilling to an exact depth, or especially [illegible] when using small drills on "through" holes. The slack manifests itself by the catching and breaking of the drills as they break through the bottom of the work and by an uneven depth of hole on the blind work. Why any maker ever started to use two No. 10 screws to fasten on the rack is a mystery; they do fairly well when new but after a year of service the screws get loose and wear the holes and then no screws can be kept tight in them. If a key were put across the rack and quill, it would take the thrust of feeding and the screws would never get a chance to loosen up. The best fitted screws would crush their own threads and those in the hole, if continually hammered, as are the rack screws. As the teeth wear and chiefly, as the pinion shaft bearings wear, there is lost motion at these points which is directly noticeable to the workman. This can be taken up by packing behind the rack or putting in new and over size parts. The proper way would be to put bushings in the pinion shaft bearings and if these were made eccentric, all wear could be taken out by re-setting these.

All the known constructions of table about the column are the split and binder type and with all of them the loosening to move the table creates a gap, which though sometimes small is always big enough to receive falling chips. Those workmen who invariably wipe all the dirt off before loosening the clamp are as scarce as the proverbial hens' teeth. Once this dirt gets in, it never gets out (unless the drill gets an overhauling) and consequently the table is tipped out of line. A wiper or scraper would prevent this trouble just as it protects the vital parts of a grinder.



WIPER TO PREVENT CHIPS FALLING BETWEEN COLUMN AND TABLE STRAP

The feed lever is usually put through a casting that is set on the right hand end of the pinion shaft and in many cases it is fastened with a set or thumb screw, presumably to allow the casting to be turned to a more convenient position for feeding. If the feed lever is made to shift through the socket, two positions are obtained which are all that [illegible] movement of the table or the head will provide any other setting to bring the lever into a handy location. This casting should be a tight fit on the pinion shaft and should be either keyed or taper pinned. The time which a boy, if not watched, will take



ECCENTRIC PINION [illegible] KEYED TO DRIVE [illegible]

to make the necessary (?) adjustments which this loose casting and the thumbscrew requires is unbelievable; the time spent in trying to keep it right after it has worn sloppy and the set screw has marred the shaft is exasperating and uneconomical.

Any workman likes to feel a snug machine under his hands. He cannot help doing more and better work when a touch of his hand produces an instant movement of the tool instead of taking up the slack in a dozen places first, like an engineer starting a heavy train of cars. These suggested changes would be mere trifles in the cost of building the machines but they would add immensely to the value to the ultimate consumer.

## DIES AND DIE MAKING

By J. D. O.

OWING to the increased demand for standardization and interchangeability of parts, the subject of dies and die-making is becoming more and more important every day, so much so that the die-maker is rapidly becoming a specialist and the demand for good die-makers is much greater than the supply. There are a great variety of dies, some of them costing thousands of dollars and even at that price they are a paying investment.

### Effect of Taper on Punch

The commonest form of die is the ordinary round punch and die used for punching rivet holes in boiler plate and other material. The amount of taper given to the punch is an important factor in the life of the punch. Some argue that the taper on a punch allows the metal to close round the punch and makes stripping harder. This does not seem to be borne out by tests and experiments that have been made. Three

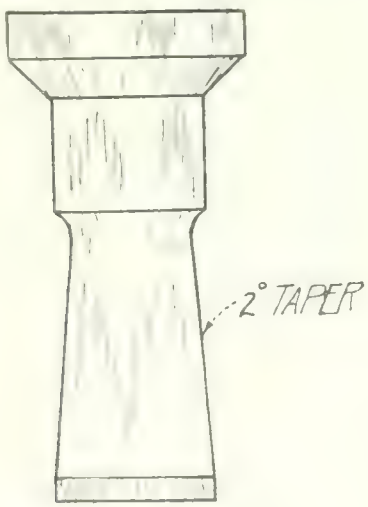


FIG. 1. PUNCH WITH TAPER.

punches 23-32 in. dia. were made, and three pieces of machinery steel 2 in. wide, 2½ in. long and ⅝ in. thick were punched, one piece with each punch. One punch was made straight, one with one degree taper, and one with two degrees taper. The three punched pieces were stripped from the punch by a testing apparatus under exactly the same conditions. The punch with a two degree taper stripped at 550 lbs. The punch with a one degree taper at 780 lbs., and the straight punch at 2,000 lbs. A punch made with two degrees taper strips easily and stands up well against breakage due to stripping. It is a well known fact that a large percentage of punches are broken in stripping; on the other hand a taper punch cannot be ground without losing its size, so that a good practical punch is made with two

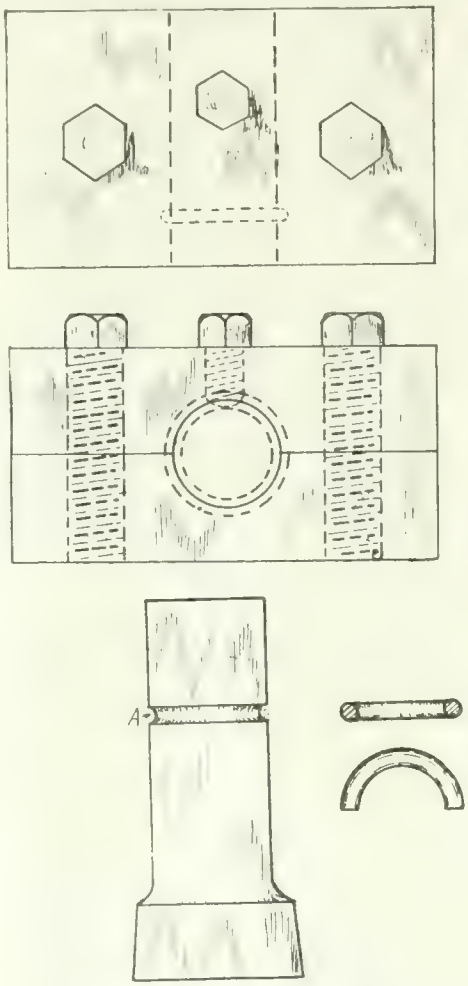

FIG. 2. RING AND GROOVE METHOD OF HOLDING PUNCHES.

degrees taper, except for a short length which is made straight to allow for grinding. See sketch Fig. 1.

### Methods of Holding Punches in Their Places

If punches are simply driven into their holders or fastened with an ordinary set or safety screw, they are apt to cause a lot of trouble by being pulled out of their holders, besides being sometimes very hard to remove when you want them out. Fig. 2 shows a holder designed to prevent the punches drawing out of their sockets and also permit of their easy removal. A semi-circular groove A is cut around the punch, while the cap or clamping plate has a similar groove cut in it. A half ring of steel wire is made to fit the combined half round grooves in the punch shank and the clamp. This ring is set into the grooves and the clamp tightened up.

Fig. 3 shows a very efficient punch holder design which has the advantage of allowing a series of punches to be

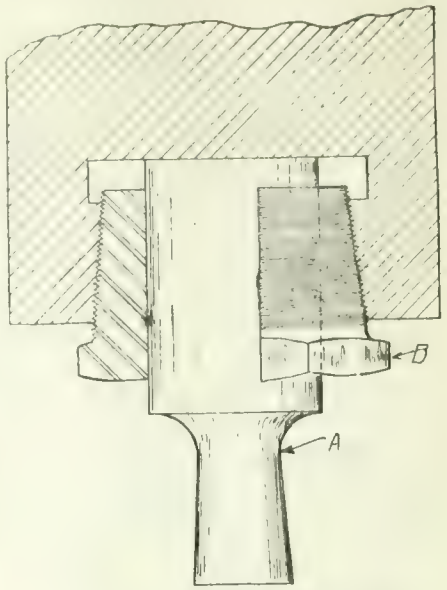

FIG. 3. A COMPACT HOLDER FOR MULTIPLE PUNCHES.

placed very close together, it also permits of any punch being removed or replaced without disturbing the others. The punch A is held in position by the threaded sleeve B which is tightened up by a special box wrench.

### Punch Stripper

Many die-makers make a mistake by paying too little attention to the stripping arrangements. A proper stripping arrangement is necessarily a very important part of the design of any punch and die. Sometimes a rubber stripper as shown in Fig. 4 is very satisfactory, it has the advantage of holding the work

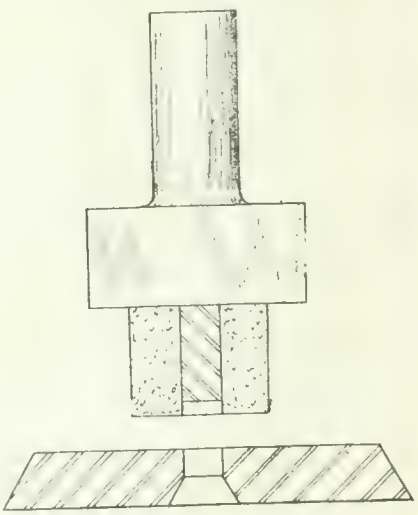

FIG. 4. PUNCH AND DIE WITH RUBBER STRIPPER.

firmly down to the die before the punch comes in contact with it.

### Cast Iron Punches and Dies

It is not generally known that in some cases a satisfactory job can be made

with a cast iron die and punch. Of course it is preferable to make the die at least of cast iron. It is often necessary, especially in a small job shop, to make a small number of blanks, but not enough to warrant the manufacture of a regular tool steel punch and die. If the blanks are not over 1-32 in. thick, the die at least can be made of cast iron, and if carefully made will produce several hundred blanks. Experiments have been made with cast iron dies in large quantities by inserting chills in the foundry; the shape of the blank perforations, if any, must be made with the proper amount of clearance. Dies made by this method cost very little, the punch being made of tool steel as usual Cast iron dies have been used for experimental motor and armature laminations producing a satisfactory type of stampings.

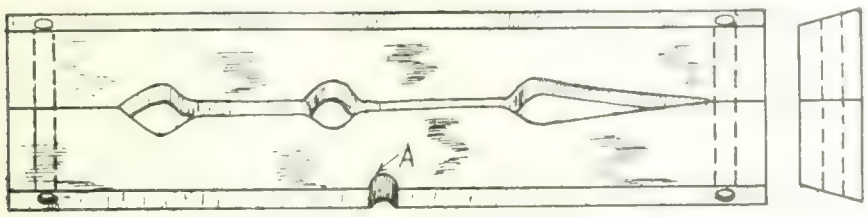

FIG. 5. SPLIT DIE FOR BLANKING OUT CLOCK HANDS.

### Split Dies

Sometimes it is much more convenient to build up a die in sections than it is to make it in one piece. The split dies shown in Fig. 5 are used for blanking out clock hands. The two sections are doweled together as shown to prevent them from shifting endwise. The semicircular notch A is to receive a round stud in the die bed and prevent the die from shifting when in use.

### Dies for Forming a Tube

This die consists of the bedplate A, suitable for the press intended to be used, the die B, the mandrel C, the punch D, and the punch holder E. Fig. 6 shows the punch up with the blank dropped in and the mandrel in position. The weight of the mandrel has a tendency to crowd the blank over against the punch and allow the mandrel to start in the die The blanks should be placed in the die with the burr in toward the mandrel to prevent the tendency to buckle back. Fig. 7 shows the die in its closed position. This die will form tubes ⅛ in. thick or less and 8 or 10 inches long. The open front is very convenient for feeding blanks, and a fork can be used at one side of the die to pull the tubes off the mandrel. It is more convenient to lift the tubes out of the die with the mandrel, pulling them off outside, than to remove the mandrel while the tube is in the die.

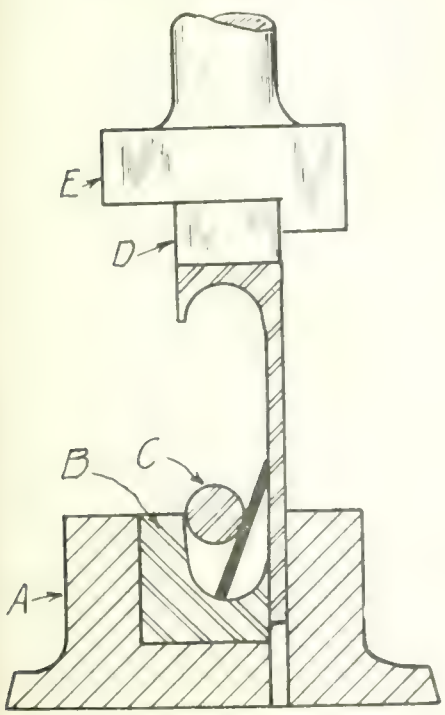

FIG. 6. MANDREL AND BLANK IN POSITION

### Practical Hints on Die-making

The method of laying out and machining a die depends mostly upon the shape, as some shapes could be finished entirely in the lathe, planer or shaper, while others would have to be done by hand or by some special milling or profiling machine or attachment. The first operation is usually to shape up the stock to the right thickness and to fit the machine where it is to be used. In taking the finishing cut leave as smooth a surface as possible, give it a rub over with a flat smooth file, then with a clean rag or piece of waste apply a coating of bluestone and water. Allow it to dry and the steel will have a copper-colored appearance, which shows up the marking off very clearly. If there are any circles or parts of circles, make very fine centre punch marks. Don't make large centre punch marks; in fact, the punch should be ground the same taper as the leg of the compass to ensure making a perfectly true circle.

### Marking Off

In making straight lines don't depend upon holding the scale or straightedge with your fingers, as it is very apt to move and cause you to make false lines. Always clamp your straightedge down and see that your scriber is sharp and hard. If the die is an irregular shape, the bulk of the material is usually removed by drilling a series of small holes as close together as possible just inside the marking which indicates the finished dimension. Be very careful in marking off the centres for these holes. You will save time in the end by doing so. Let the outer edge of the circle come within 1-64 in. of the finished dimension marks. If the drilling is carefully done, you will have no difficulty in removing the metal required unless the holes drilled are too small. In that case the thick part of the chisel would bind in the hole before you drove it half-way through the stock. The size of the holes would be decided by the thickness of the stock. For an ordinary blanking die 1 in. thick I have found 3-16 in. holes the most satisfactory.

### Putting on Clearance

After getting out the metal, as just described, it will reduce the amount of work in finishing if clearance is now put on the die. If an end mill and milling machine is available, turn the die upside down and mill about 1-16 in. outside the finished lines, leaving about ⅜ in. of thickness for finishing; this leaves very little material to remove for finishing. Finish now with the best means at hand, often with a file, leaving a taper of 1 deg. for clearance. If there are any holes to drill or tap or any other work, finish the die completely and harden before starting to make the punch, as the die is more likely to alter its shape in hardening than the punch is. The die is now used for a template to mark off the punch. As the die is now hard and the punch soft slightly tapping the punch into the die with a hammer leaves a clear impression, showing where to file the punch in order to make it fit.

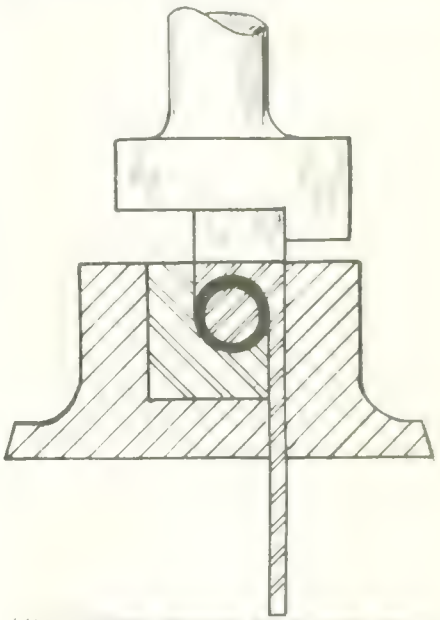

FIG. TUBE FORMED BY CLOSED DIE

## GENERAL HINTS FOR MACHINE SHOPS

By J. Davies

if not impossible, proposition. There

holding down, the wear of the tool, sand holes in the casing, spots of scale, etc., to say nothing of errors caused by the carelessness of the machine operator. To correct work of this kind scraping

over again. Good scrapers can be made from old smooth files, if they are of the right shape and can be used without rehardening. If they need to be reshaped and rehardened they are not very satisfactory.

### Scraping Plane Surfaces

Scraping is usually done in the following manner; brush off any dirt or dust and rub a smooth file over to remove any burrs. A surface plate thoroughly cleaned and coated thinly with marking material is placed on the work and carefully rubbed over the entire surface. No pressure on the plate is necessary the weight of the plate being sufficient. When the plate is removed patches of marking will be found on the work and these marks indicate the high spots, which are removed by the scraper and the process repeated until the surface plate marks the work over the entire surface. In the making of a surface plate or straightedge, unless you have a master plate that you can absolutely depend on, it would be necessary to make three of them. Two plates or straightedges may fit each other and neither of them be straight but if three surface plates will fit each other, that is if any one of them will fit the other two then they must all be perfectly flat.

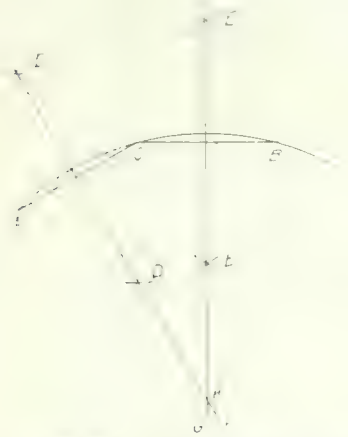

FIG. 1. METHOD OF FINDING DIAMETER OF CIRCLE FROM GIVEN ARC.

### Given the Arc, to Find the Diameter of a Circle

It is very handy sometimes to be able to find the original diameter of a broken pulley or wheel from a small piece of the outer rim. First divide the portion of the circle that you have into two parts as shown in Fig. 1. It is not necessary that the two parts should be of exactly equal length. Now set the dividers to any length and from the two points marked A and C make the four short lines D and from the intersection of the lines D make the line F. Then [illegible] B make the four short lines marked E and from the two points where they cross make line [illegible] F and G cross marked H indicates the correct center of the circle.

### Laying Off Circles on a Flange With Centre on Raised Boss

If you have a piece of work such as a cylinder cover, a gland, or any casting with a raised boss as in Fig. 2, and it is desired to lay off a bolt circle on the flange to given dimensions, the setting of the dividers may be found thus.

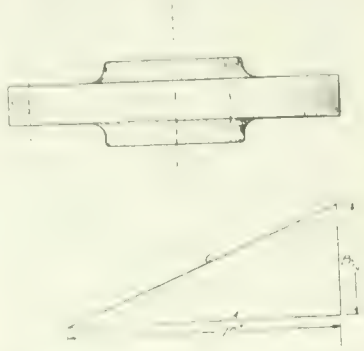

FIG. 2. METHOD OF LAYING OFF CIRCLE WITH CENTRE RAISED ABOVE WORK.

The center of the bolt circle is 10 in. from the center of the boss, while the top of the bos is 2 in. higher than the top of the bolt circle. Take a 2 ft. square or straightedge and and scribe a line A B on a surface plate or flat piece of tin, making the line B at right angles to line A, with line A 10 in. long and line B 2 in. long. Draw the diagonal line C joining A and B then set your dividers to length of line C and you have the exact radius for laying off the circle.

### Broaching or Drifting

By these terms is meant the process of forming or finishing regular or irregularly shaped holes in metal by pressing or driving a cutting tool of the exact form through holes that have been previously drilled and roughly formed to the required shape. As much of the stock as possible should be removed by drilling.

The simplest application of this method is in broaching a square hole such as that in a chuck or tap wrench. Suppose a square hole is to be made in the end of a piece of round stock as in Fig. 3. Draw a circle as large as can be made inside the square then lay off the square. Next drill 4 small holes about ⅛ in. in the corners just touching the sides of the square. The large hole is next drilled which leaves the drilled holes as shown in sketch. Care must be taken in drilling the large center hole or the drill will run toward one or other of the small holes. In some cases it is advisable to plug up the small holes, especially in the case of awkward shaped or irregular holes. A square piece of steel shaped and tempered may now be driven in the holes.

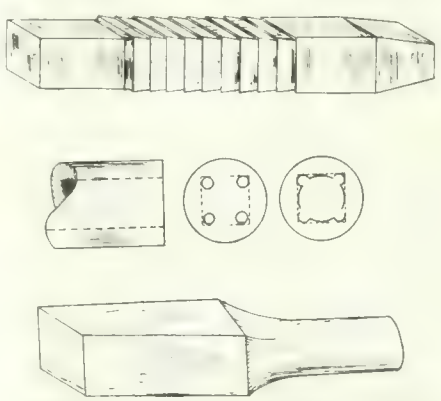

FIG. 3. BROACH AND DRIFT USED IN FINISHING SQUARE HOLES.

A very handy, quick and rough and ready method for forming square holes is to drill the hole to size across the corners, so that a piece of square stock will go in the size required. Then heat up the stock and flatten the sides to fit the square using the square stock as a mandrel.

For repetition work or machine broaching, the broaches are usually made with a number of cutting edges, with a piece turned at the end to fit the largest hole that can be drilled in the stock, this acts as a pilot. The teeth are all made the same size so that only the leading teeth cut and those behind steady the broach. As the leading teeth become too dull they are ground back below the size and the next set of teeth are used for sizing and so on until the broach or drift is worn out.

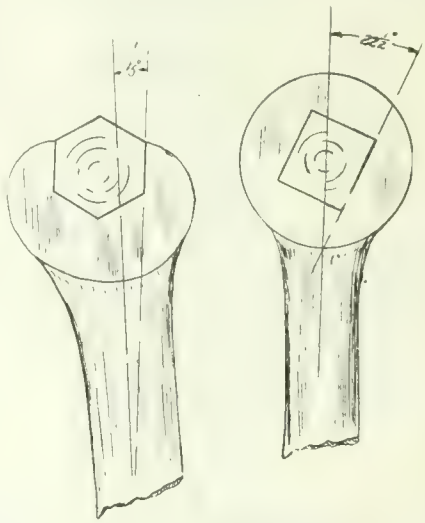

FIG. 4. ANGLES OF OFFSETS FOR HEXAGON AND SQUARE WRENCHES.

### Changing Emery Wheels

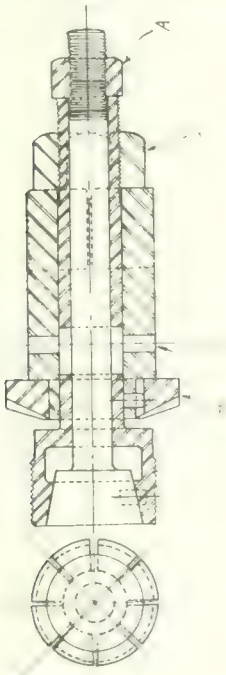
When standing before a grinding machine with the emery wheels revolving towards you, that wheel at the right hand end is held on with a right hand threaded nut and washer, and the emery wheel at the left hand is held on with a left hand thread, that is assuming a machine with a wheel on each end of the same shaft. So that to take off the nuts, it is necessary to turn in the direction in which the emery wheel is revolving.

An exception to this rule would be the case where the wheel turns on a stationary shaft. Such an instance is the buggy wheel rotating on a stationary axle where the nut is always turned in the same direction the wheel revolves in

travelling forward for the purpose of tightening it.

### Making Wrenches

Wrenches as a rule can be bought from the manufacturers much cheaper than they can be made in the ordinary machine shop, yet for the sake of convenience or for a special job it is often desirable to make one for one's own use. When this is the case they might as well be made right as not, the principal requirement of a good wrench is that it will turn a nut in the least possible space. For hexagonal heads or nuts the jaw should have an offset of 15 deg. so that by turning the wrench over, the nut will be advanced one sixth of a revolution in two moves, which is the least



REAMER FOR FUSE HOLE BEVEL.

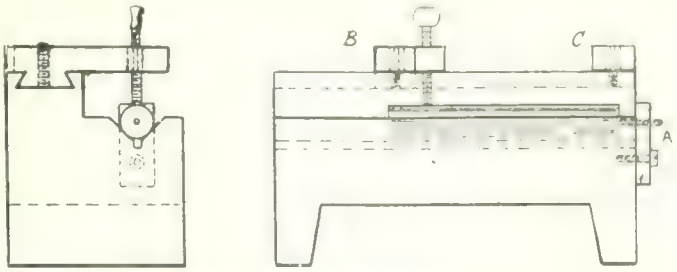
possible movement that the wrench would make. This is a very desirable feature in surmounting obstructions when working in cramped spaces. If the wrench is intended for square nuts or set screws, box wrenches etc., the angle of the offset should be 22½ deg. as shown in Fig. 4.

### JIG FOR COTTER-PIN HOLES

By J. E. Cooley

In drilling holes for cotter-pins on the end of short rods and shafts, separate jigs are required for the different diameters of these parts. The jigs used usually are in the form of a square block which is slipped on over the ends of the stock to be drilled. The work involved in putting these on and taking them off, besides squaring up the blocks, requires considerable time.

In the sketch is shown a design of an adjustable drill-jig for this purpose; made a sufficient length to take in a limited number of different diameters and lengths of rods and shafts. The jig has a Vee cut across the lower side to hold the work. At the end of this is a steel piece (A), having a stop-screw for locating the distance in drilling the holes on the end of the work. On the top edge of the jig is a dove-tailed groove in which the drill-bushing pieces (B) and (C) are made to slide and set where desired. The headless screw in these is



JIG FOR DRILLING COTTER-PIN HOLES.

turned down to hold them in place. Piece B is made wider than C, in order to take in a thumb-screw for holding down the work in place, as shown.

### MACHINE OIL VS. AUTOMOBILE ENGINE OIL

By D. A. Hampson

A screw machine that had been running 1,800 R.P.M. was put on a brass job and its speed increased to 2,600 R.P.M. It gave continual trouble in the main bearings—heating up, sticking, stopping. Plenty of good "machine oil" had been used but that made no difference. When automobile engine oil was tried the the trouble stopped right away and the machine ran as well as at the lower speed.

### THE SUCCESSFUL TOOL DRESSER

By J. R. M.

THE success of a certain tool dresser, known to the writer, was his knowledge of human nature and a careful study of the men who were continually using the different tools he was called upon to make and temper. He did not follow the general practice of tempering the tools to set standards of color, or degree of hardness, but used his judgment in making the various tools to suit the particular workmen that were called upon to use them. He was of the opinion that a smith should adapt himself to the special needs of the individual operator and guide his tempering of the tool to correspond to the ability of the user. A skilled mechanic, who knows how to grind a tool and use it properly, will use a much finer and higher tempered tool than another man or boy less skilled in these essential requirements. A smith who can adapt himself to such conditions is assured of greater efficiency from his output from the forge.

### SUCCESSFUL SEA TRIP BY CONCRETE SHIP

THE first concrete ship has made a round trip and sailed into its home port, after a successful voyage. It is a Norwegian vessel, caled the Nansenfjord, and has just returned from the British Isles, after having steamed two thousand miles. This ship was built several months ago, and is made of structural steel and concrete. It is said to have answered every test satisfactorily, unaffected by the vibration of the engines and notwithstanding the jamming which a ship frequently receives when it is docked. Also it shows no ill-effects caused by contraction and expansion. The vessel is of the single-screw type, driven by a heavy oil engine, and has a displacement of about five hundred tons.

### STEEL PLANTS CLOSING FOR LACK OF RAW MATERIAL

THE extent of the depression in the steel industry in the United States as a result of inability to secure raw material is reflected in the fact that only nine of the U.S. Steel Corporation's furnaces in the Chicago district are in operation out of 29. Conditions are about as bad in the Pittsburg district.

Steel manufacturers will put up a strong fight against the movement in Washington to force another readjustment in steel prices. In December domestic consumers were liberal with their orders because prices were adjusted up to April 1. Now that another adjustment is talked of orders have fallen off in the belief that any change will be downward. The plan to establish a different set of prices for each producer, based upon cost of production, is not liked by manufacturers, who take pride in their low costs. They feel that, having brought their plants up to a high state of efficiency, they should not be compelled to accept the same margin of profit as the high cost companies.

### PANGBORN CORPORATION PRESENTS EMPLOYEES WITH LIFE INSURANCE POLICIES

EMPLOYEES of the Pangborn Corporation, Hagerstown, Md., were presented at Christmas with life insurance policies, ranging in amounts from $500.00 to $1,000.00 according to length of service. The Pangborn Corporation bears all expense of maintaining the insurance and all the employees have the satisfaction of knowing that their near and dear ones will be provided for in this amount in case of death.

**Standard Ship Launched.**—The second of the 8,800-ton standardized steel merchantmen under construction for the U. S. Emergency Fleet Corporation was launched recently at a Pacific port thirty days after the first launching and sixty days after the keel was laid.

## ORGANIZED KNOWLEDGE AND NATIONAL WELFARE

By O. C.

THE future of any nation is secure if it lives up to its possibilities and develops to the full its natural resources, which development can be only accomplished through organized knowledge. It is essential to an individual, to a firm and to a nation that its organized knowledge should be kept up to date by constantly increasing and applying this knowledge. To accomplish this, interest in research should be constantly kept up, and much research in all branches of science be kept going. This should be done not only in physics, chemistry and engineering, but also in the biological and mental sciences. Increase in knowledge in the field of biological sciences means more and more better food, improved public health and increased material welfare. Better knowledge of the fundamental principles of the mental sciences means increased efficiency in administration, legislation, education, operation and research.

The research by which organized knowledge is increased will doubtless always be carried on by three distinct types of research organization; research by the government in national laboratories, research by the universities in connection with instruction, and research by industrial laboratories in the interests of manufacturing firms. National research includes such problems as standardization of measurements, guardianship of the public health, and those connected with contagious and vocational diseases. It has to deal with making good roads and increasing the fertility of the soil, as well as with matters merely relating to lessening the cost of production. University research must always be chiefly concerned with the advancement of the various sciences as such, and the development of the fundamental principles of each science. Industrial research takes the middle ground and has already become a distinct profession. Its proper field has to do with the elimination of works troubles and the investigation of fundamental principles. This brings up the question of the ideal research man and ideal research laboratory. A large number of students are really fitted for research work if properly trained along the right lines, and thus might be evolved the ideal investigator, who should have a mind at once fertile and well trained. His mind should be trained to have unerring judgment and to reject ideas which are not logical and promising.

### Desirable Training

The best training for a research man is a thorough grounding in the fundamental principles of his science, physics, chemistry, or whatever it may be. If he has this, it is safe to say that in any properly organised research laboratory, under proper leadership, the student will have many more useful ideas than he can himself possibly follow up. Fertility of mind is not so much an inborn quality of the mind itself as of the training and association which that mind has had.

The ideal industrial laboratory consists of two quite distinct divisions, one doing all the works testing and analysis of materials and the other dealing with large fundamental problems, requiring skilled specialists and considerable time for their solution. The alternate plan, having a single research laboratory covering both works troubles and new problems, is not so successful, as the new work is liable to be interrupted whenever a special press of works problems comes in, and is therefore less efficient.

Industrial research is best carried on by team work. Thus two, three or more men work together on the same large problem or group of problems, the aim being to have a good theoretical man, and a good practical man working together as much as possible, or even a physicist and a chemist in some cases. The important point is, however, to have regular conferences of the men working on the problem, say once a week, to discuss it, to plan new work, and to consider the various interpretations and applications of the results obtained.

The conferences may also be attended by a member of the legal department, who will take in hand any ideas worth patenting, and also by a member of the works wing of the research division who will look after the application of any results that have reached a sufficiently completed stage. In this way the specialists are relieved of the responsibility of directing the attention of the works and of the patent department to useful patentable results.

### Closer Touch Wanted

It is a crying need, as far as national welfare is concerned, that professors and teachers should be in closer touch with industrial problems. The ideal instructor for a research student is a man who has already carried out research work along industrial lines. It is also necessary that there should be more co-operation amongst the various branches of research—national, university and industrial. When the problem in the research department has been worked out it has then to be transferred to the works, and it is here in applying this knowledge that the engineer takes part in the scheme. It is of as great importance here as for the research man that the engineer should be fully trained and possess a special knowledge of fundamental principles. It is the engineer who, when he experiences troubles in the work, carries back his troubles for the research department to elucidate. He must also possess a knowledge of those fields of work related to his own special field, in order to become more fully competent.

Research is one of the youngest of the professions. It is of vital importance that students who are to follow research should be thoroughly and efficiently trained, and that they should not embark upon it without thorough knowledge of its aims and methods.

## EFFICIENT SHOP INSPECTION

By M. H. Potter

INASMUCH as munitions of war must be accurate within very low tolerances, Canadian manufacturers have lately been confronted with a more or less new and complex proposition—namely that of inspection. Furthermore a large number of manufacturers have found that inspections pays, that it not only increases the quality of their product but also lowers its cost. They have therefore applied inspection to their regular routine.

In order that the reader may clearly follow the inspection as here outlined the following classifications are used: the chief inspector, head inspector (in direct charge of one department) examiner (to check the work by use of "go" and "no go" gauges).

### Chief Inspector

The chief inspector must have the full confidence of the engineering department and always be in direct touch with this department. This will enable him to know exactly those parts which must be held to close limits and those which need not. This not only means more rapid production but gives the operator the knowledge that the examiner is there to help him and not to interfere with or delay his work. The latter is of utmost importance as the average operator invariably looks upon the work of the examiner as a necessary evil and takes it for granted that delays will result. The head inspector should be posted to guard against and finally eliminate this great barrier which at present exists. The chief inspector must therefore work for common sense but rigid inspection; when it is adhered to, the operator soon becomes acustomed to it, learning that only good work will pass and making every effort to produce it.

The chief inspector must insist upon the daily reports being kept up to date and accurate, having one or more clerks to handle these. The heads of the vari-

ous departments by consulting them know where the hold ups are. They also point the way to the operator who cannot produce satisfactory results. The engineering department often learns much through these reports and by changing the design or altering the functions as first laid out avoids repeated delays. It can therefore be readily understood that a properly managed inspection department is a great help to all concerned inasmuch as it is the key to the solution of almost any trouble that may arise.

### Qualifications for Inspector

The head inspector must know the work of his particular department and be able to replace the operator in order to have the confidence and good will of the operator. Otherwise the proper spirit, which as previously pointed out is so essential, will not exist. He must be a practical man. In making appointments or filling vacancies the following should be taken into consideration; that the alert, progressive operator can be trained to inspect the work he has been doing far better than an inspector who has been inspecting different work.

Naturally a good inspector can take charge of the inspection of most any work but should not be called upon to do so. If he is to have the responsibility of the work in his department he must be paid a little more than the operator whose work he inspects. Then again, this makes the position a desirable one. He should be paid by the week and entitled to all the privileges of such an employee.

Many opportunities to increase production are available to the head inspector and the right man will often make suggestions along this line which will bear investigation. By observation, provided he understands the work he is inspecting, he is able to make such recommendations. Drilling along this line must be continually aimed at and should be one of his requirements.

### Employment of Girls

Girls have almost taken the place of the male examiner; when properly handled they work faster and will do the same work for less pay. The hourly basis of payment is satisfactory—the piece work system should never be resorted to. Whenever possible they should be separated from the operators and so confined as to be able to concentrate their minds upon the work. If unable to handle one gauging, they should be transferred to another department and given a second trial. In this way the best results can be obtained. An eight hour day should never be exceeded under any circumstances.

### Tool Room Application

The foregoing applies to general manufacturing. If tool room work is involved, a jig, fixture and template inspector must be employed. He is not only required to check the work but must also be capable of judging the design from the blue prints. It is customary for the designer to consult the inspector and submit his designs for criticism before proceeding with the work. The tool inspector must be a practical tool maker in every sense of the word and have enough executive ability to command respect.

## FILLING UP ODD TIME IN THE FOUNDRY

By T. J.

IN most foundries it occasionally happens there is a slack interval in which it is inadvisable to put off the moulders and other workers, but still there is difficulty in keeping them employed sufficiently to cover expenses. At such periods some form of work, which might be called "stock work," is very desirable, and in regard to this there are many domestic castings that can be turned out at a moderate profit if anyone cares to look around. There is always some demand for iron wheels for toys, such things as false bottoms for grates, door and garden scrapers, and other things readily made with no very high grade metal, and higher up there are ornamental castings both easy to make and selling regularly in the retail trade. To assist in the selection of goods to make, get hold of a few illustrated hardware catalogues, and see what can be produced cheaply, bearing in mind that as nothing was being made to order, the stock would have to be made in slack times to meet the orders as they came.

Having made what might be thought a good selection, the drawings should be taken to some distributing house and terms arranged with them for the goods; they will probably purchase certain stock quantities at various times, sending out in small lots as their orders came in. At the price charged to retailers for much of the ironwork there is room for good profits to both makers and dealers, thus making the matter well worth consideration. In brass and other metals there are a good many outside items that can be made to fill up odd times and which can be done with scrap metal as a rule, so long as it is run down of one color, and beyond this mere foundry work machined work can be produced where there are facilities for doing this cheaply in slack times; some kinds of toys, and what may be called puzzle locks, not being despicable as a small means of paying wages as well as the cost of material, all however, depending on cost of production. Necessarily, the workmen must assist in filling up the time to the best advantage without slacking; but usually they will take advantage of this kind of work rather than stand idle, that is, if proper explanations are given to them.

## 95 PER CENT. OF VETERANS FIT FOR FORMER WORK

CONTRARY to the general impression created by the emphasis which is laid to-day on the awful mutilations of the present day warfare, the great majority of the soldiers returned to Canada unfit for further military service and discharged have been able to return to their old occupations and carry on in civil life. In fact the number who must be educated in a new line of work represent only 5 per cent of those who have come back, according to the figures of the vocational training fyles in the Military Hospitals Commission headquarters.

A few men unsettled by the irregularity of military life want to switch to some new line of work, but the average man, detained in the convalescent hospitals in Canada for further medical treatment, is anxious to get back to his old job.

### Back To The Old Job

"What are you going to do when you are discharged?" one middle-aged man was asked.

"Do?" he echoed. "I'm going to do what any sane man of my age would do. I'm going straight back to work. This is just marking time in one's life, like having to go to a wedding on one's busiest mail day. I'm not going to exploit the war as a means of getting a living, or emigrate, or do any fool thing like that. I am going straight back to my office, I am. I know exactly where I turned down the page of my sales book when I came out—it was page 79—and I'm going to start again on page 80."

## CANADIAN UNIVERSITIES AID IN REHABILITATION

CANADIAN colleges and universities are doing much in the work of the rehabilitation of the Canadian soldiers who have returned from the front disabled for further military service and requiring further education to enable them to carry on.

From coast to coast in every province the higher educational institutions have demonstrated their willingness to do all in their power to help in the work of re-education. Faculties in all departments in which soldiers have required work have been eager to do their bit by co-operating with the vocational training department of the Military Hospitals Commission in adapting courses for their needs.

The advantage and economy in both money and time to be gained by using existing facilities is readily evident. The university plants for technical training are ideal, although the courses have to be adapted to shorter periods of time. The University of Toronto, McGill, Queen's, the University of Saskatchewan and University of British Columbia have all taken an active interest in the work.

Courses have been arranged to provide instruction in motor mechanics, machinist work, tool making, pattern making, electrical work and telegraphy.

In some instances the vocational officers have arranged for men to complete arts courses, and in others men who had started to be scientific farmers have been given courses in agriculture.

# Business Problems During and After the War*

By Judge Elbert H. Gary

*How [illegible] ordinary interest attaches to deliverances by the notable author of the following remarks. As head of one of the largest industrial corporations in the world, whose activities and resources are of vital influence in reaching a verdict in the war, the expression of his views on present and future problems is most timely, covering as it does the principal phases and possibilities of the situation..*

THAT Germany is more virile, more efficient, more determined and more aggressive than she was at the beginning of the war, and that as a nation, if she wins in the near future, she will be stronger financially, industrially, commercially, militarily, and with a comparatively small reduction in the number of men, notwithstanding the loss of millions of soldiers, was a striking statement by the speaker.

Our country, as a whole including the several branches of Government, does not yet appear to appreciate that in order to win in this war it is necessary to appropriate every ounce of energy, every dollar of wealth and every atom of skill within reach, to be drawn against when needed; and to offer every sacrifice, even of personal opinion or pride or desire for advancement of the interests of individuals or political parties. Of course every one has decided that every other person ought to subject personal ambition to the demands of the public welfare; but large numbers go no further. This includes you and me, and it does not exclude others occupying more conspicuous places in the nation's registry. But this is only one side of the canvas.

If we are going to continue in the war against Germany, with all her power, we may well ask ourselves what is necessary for a defense against this modern monster of despotism, tyranny, destruction and oppression; and also whether or not we are able to meet the requirements.

Various branches of activity, all essential to final success, such as food, transportation, arms, barracks, aircraft and seacraft and the money necessary to provide such resources were dealt with, after which the subject of labor received attention.

### The Problem of Labor

Labor is scarce and growing more so, although there are employed large numbers of American women who are doing their full share, in both civil and military lines of activity, in accordance with their strength.

Now it is manifest that in order to render the assistance that is asked of us and which seems to be imperative, we must have more and more men, for soldiers and workmen, skilled and unskilled. We cannot produce the quantities or amounts demanded unless the number of men is materially increased, nor unless all who are willing to work are permitted to do so to the extent of their reasonable capability and desire. There is a shortage of labor in this country at the present time on the farms, the railroads, the ships, in the shops, the factories, the mines, the offices. Production even up to the present capacity cannot be secured unless more workmen are employed. And for the building of increased productive capacity and for the operation of the same, additional men must be procured.

We may be excused for having been slow in getting ready for defense against unjust attack, even since August, 1914, but there can be no justification for failure in the future to push vigorously and without unnecessary interruption, in every department of the Government, preparation for assisting the allied forces to carry on and to win the war by the utilization of everything that is valuable for war purposes. Expenditures had better be too large and preparation overdone than to risk the danger of neglecting to provide any single item that might add to the military strength of the allied forces.

### The Weakest Spot

The weakest spot in our situation is lack of sufficient production of the things that are vital to the life and strength of the armies, which might be obtained except for the scarcity of labor. It would be unwise, nay, unpardonable, if this shortage shall not promptly be overcome. This question at present is of commanding import.

This country has an advantage over all others in times of war or peace, by reason of her natural resources and accumulated wealth, but it is not of full practical value unless the agencies for production and use are sufficient. To the extent that workmen are lacking in number, to a corresponding degree are wealth and raw materials without value. It is questionable whether, when an abundance of ships is built, there will be trained men and machinery in ample numbers and quantities, and, in the case of battleships, adequate supplies and munitions.

### Duty to Labor

The labor question is one which employers are sometimes reluctant to discuss for fear of misinterpretation of motives, but in war times every question which bears vitally upon the conduct and termination of the war should be considered frankly and fairly by the employer, the employee and the public generally. Each is equally interested. Each is entitled to protection and the rights of none should be neglected, although the necessities of the general public are always of primary importance.

Lest anyone might conclude that I have in any respect changed my views as heretofore expressed concerning labor generally, I may be permitted to say: Workmen should always have fair, just and liberal treatment. They should be paid good wages, taking into account the service rendered and all conditions which reasonably apply. The welfare, safety and health of the men and their families should receive careful attention by employers. Relief funds for the result of accidents or old age should be established. All men, of all grades, ranks and nationalities, should be permitted to work when and where they please and on terms that they agree to. The laws should impartially protect both capital and labor and permit imposition or abuse by neither.

The precarious conditions, already adverted to, compel the United States to do everything within its power to bring the war to a speedy and victorious close. We insist our soldiers shall not be placed in the trenches or on the firing line unless and until they are completely hardened, trained and equipped, and that they shall always be furnished with sufficient supplies to protect them and preserve their health. The fathers and mothers of this country have given their sons in defense of our beloved land. These men are entitled to every practicable effort on our part to assist them, and this without one moment of unnecessary delay. Efficiency, abundance and promptness will save millions of men and billions of money.

### Need for Man-Power

To the extent needed for the purposes named, the United States should immediately, under proper conditions and reasonable restrictions, draw from the islands of the sea and from oriental countries, enough men including soldiers and sailors to meet every emergency. There would be no difficulty in obtaining within a short period large numbers of strong, healthy, intelligent, loyal men for civil or even military duty, and the number could be increased from time to time as required. All who are acquainted with the facts know that we need more men and that we can get them if we are so disposed. If legislation is requisite, Congress should act without delay.

There may be, there already have been, objections to the admission of certain nationalities, even temporarily and under carefully considered restrictions.

*Abstract of address delivered before the Com[illegible]

These have been persistent, especially by foreigners who heretofore have settled in this country. But the thing to do first is to win the war; to stop the spilling of blood, the destruction of the lives and health of our noble and loyal men and the unjustified depletion of our resources. We can discuss and properly decide other questions later. If we now delay, we may not have the opportunity to consider the other matters.

And still, if objections are raised and discussed, they can be fairly met and with good reasons, in addition to the one war's necessity, which is undebateable. At any rate they are not fundamental nor of much consequence by comparison.

### Confident of Victory

We believe the war will end victoriously for the allied forces within two or three years; we hope in a much shorter time. It could not terminate in favor of the other side within a decade, for, with all the means at our command we would fight for that period or longer before we would submit to the despotic rule of an autocratic [illegible]

So sure are we that we will be perfectly organized, that the management will be of the highest order and that the war will be brought to a successful conclusion that we are justified in considering with care and anxiety the world's business affairs growing out of and following the war.

We shall be met with the fullest preparation and the fiercest competition on the part of the others and we must likewise be in condition to protect our interests and to push our claims for a fair share of the world's business. There will be an opportunity for economic progress, which, if neglected, may never return.

### Future Aspects of Trade

Legislators, as well as business men, should, even now, give heed to future trade problems, for of great importance is legislation which will place our country on a parity with all others in the protection of our domestic trade and the extension of our foreign commerce. Other governments will, by legislation, aid, in every proper way, their business interests to expand and prosper—many have already arranged for this; and our government should do likewise. An intelligent persons seeks opportunity to profit by experience of others.

Neither Germany nor any other country, whose home industries are fully protected, will hereafter be permitted to enter the markets of Great Britain, except on a basis of equal or reciprocal protection, depending upon all the circumstances, including the products involved. There will be careful study and scientific discrimination, all with the single intention and effort to secure every proper advantage. The theories of the past, based on habit of thought, and conditions which have disappeared, will be swept aside and principles more practical, more selfish and more useful will be substituted. England for the [illegible] English will be the national slogan, as it ought to be.

From the same motives and for the same reasons, American industry must be protected, not unfairly, not to the prejudice of the general public nor to the point of permitting abuse or oppression of any interest, but to the limits of reason and honesty, all things being considered. Laws which will secure just prices to the consumers, reasonable profits to the producers and to the transportation companies, and fair wages to the workmen, all based on inquiry and study, should be the aim.

### Merchant Marine Necessary

To compete with other countries we must have a merchant marine equal in every particular to the best, with every advantage and no disadvantage in comparison with any other, unhampered by laws, rules or regulations which might interfere with practical and successful business operation. We should be prepared to deliver the surplus of everything we produce at the doors of non-producing countries in packages and on terms satisfactory to those who desire to purchase.

Our merchant ships must never again be compelled to haul down the American flag or to occupy an inferior position in the international struggle for economic excellence and advancement. Americans, if given an equal chance with the people of other nations, will furnish business to comfortably support a merchant marine excelled by none.

If there be established, maintained and effectively executed a basis for equitably disposing of all international disputes by arbitration, a very large navy for the enforcement of legitimate civil rights will not be necessary; but in any event, the United States should maintain a navy of sufficient strength to protect her commerce in every part of the world. Heretofore it has not always been absolutely independent and safe, notwithstanding what may have been said or written to the contrary.

### Constructive Policy Demanded

Of high importance is the maintenance of a constructive policy by our government, one that is calculated to build up, to extend, to increase efficiency. It has been demonstrated that concentrated wealth, integration of industry, large units, big and capable organizations are not only valuable but indispensable in times like the present; and they are proportionately so at all times. When large quantities, highest quality and efficient and prompt execution are requisite, the demand for supplies can be properly met only by large resources and capacity. Small unintegrated or disintegrated or impoverished productive agencies are not adequate.

The railroads in certain sections of the country are a striking example of the imperative need for additional tracks, equipment and terminal facilities which money alone can provide, and this in [illegible] been expended for these purposes. It is a pity that they have not been pecuniarily able to make full preparation to meet the emergencies of the present time, for there is a marked deficiency in railroad capacity. They need a good deal of additional money, and they should be allowed tariffs large enough to furnish it.

And all this applies with equal force to a post-war period. To occupy a proper place in the world's economic forum, our country, by a wise policy, should permit, and even encourage, the building up and maintenance of wealth and of production and transportation capacity proprotionate to the great and increasing resources of the country as compared to other countries. Abundant manufacturing and transportation facilities on land and sea and lakes, supported on a living basis, ably and properly managed by private interests, are what a prosperous country should have.

### Past Policies Deprecated

During the last decade or longer, in varying degrees, the policy of the United States has not been favorable to conditions which, at present, are deemed wise, proper and necessary.

The policy of Germany, and, in less degree, of other nations, has been to construct, to build up, to extend, to enlarge, to foster enterprise and to protect industry; while our policy has been, in a measure at least, to disorganize, to disintegrate, to prevent, to limit and even to destroy. For this reason Germany to-day has a military organization and a business organization ahead of all others, and this has prolonged and will further prolong the war, notwithstanding the superiority of her enemies in wealth, numbers and other resources. We should be placed on an equality. It is not intended to convey the idea that unbridled license to concentrated business is advocated; quite the contrary. In these matters, as in all others, there should be authority for governmental investigation, supervision and control, non-partisan and subject to judicial interference and correction for proper cause. Abuse and oppression by the public or the individual should always be preventable by law.

All expenditures that are being made at the present time nduer government direction, so far as possible without interfering with or minimizing their value for military purposes, should be made in view of and in accordance with the requirements of business enterprise after the war. In the adoption of designs, in the method of construction, in quality and quantity, those in charge can often, without detriment, change and improve suggested plans for the benefit of service in times of peace. This question, at least, should be in the minds of the builders and the purchasers when contracts are concluded.

### Loyalty From All

Speaking to and for that part of the business fraternity comprised of capital-

ists and employers of labor and their representatives, I urge that during and after the war, by our attitude and conduct, we demonstrate a spirit of loyalty to country, or adherence to the principles of justice and honesty; that we exhibit an intention to observe the requirements of law, to recognize the rights of competitors, customers and the general public and that we treat our employees considerately, fairly and liberally. Our practices must be in accordance with the highest ethical standards. Thus, up to the measure of our deserts, will we be entitled to the confidence and to the cooperation of those in authority.

I believe all things requisite will be demanded by the people of the United States for its and their protection and advancement, during and after the war, and that the demand will be crystallized into a governmental policy; that it is generally realized we have reached a crisis in our history; that disaster threatens; that it may be averted if we do not hesitate or quibble over nonessentials; that America for Americans will also be our national watchword; that laws will be passed, or repealed, whenever necessary to aid in securing peace and to give every interest, big or little, and every individual, full opportunity to live, to progress and to prosper.

**Optimism Paramount**

Therefore, I am an optimist, even in these times. There is, as always, a silver lining to the clouds which now obscure our vision. We need not despair. We have reason to be hopeful. There is sunlight beyond. Right will prevail over might; and reason will overcome madness. We shall be victors in the mortal combat that rages, and afterwards our country will make longer and faster strides in the struggle to maintain a deserved and satisfactory position in the ranks of nations. The business men of the United States, in the management of their affairs, have reached a high level of efficiency and moral excellence. They are at present of incalculable assistance to the Government and they may be depended upon to do their part in restoring the world's equilibrium after peace shall be proclaimed. We are proud of our country. Let us continue to give our country reason to be proud of us.

## WHEEL MOUNTING FOR CYLINDRICAL GRINDING

By Howard W. Dunbar

WHEEL breakage on cylindrical grinding operations is serious for two reasons:

(1) Probability of injury to workman.

(2) The loss of an expensive wheel and stopping of production.

There are many causes for wheel breakage, among them the improper mounting of the wheel on the wheel collar or sleeve. Writing in "Grit and Grinds" the author states that mountings for wheels, or wheel sleeves and collars as they are commonly known, take many different forms depending on the type of wheel to be mounted and the amount of grinding to be performed, but all of them employ the same general principles. Ordinarily in sleeves with small holes, 5 in. for example, the sleeve and the collar grip the wheel on the two outside surfaces so that the collar and mounting extend outside of the width of the face of the wheel; in other words the wheel is not countersunk around the hole to receive the flanges or wheel collars. This is the common type of wheel mounting for general purpose cylindrical grinding.

On special operations other types of mountings are provided which include wheels having large diameter holes and wheels with the sides countersunk so that the wheel is recessed and the mounting is set into this recess, allowing the side of the wheel to pass by any portion of the object being ground which extends out beyond the ground surface.

Cupped, dished, cylinder and ring type of wheels all have their mountings which are peculiar to the wheel and the function that it is to perform. These various forms of wheel mountings, as above stated, employ the same general principles for holding the wheel. In some instances the gripping surfaces are covered with a lining of soft metal, the object of which is to imbed itself in the rough grain surface on the wheel, forming a good gripping medium for holding the wheel in place, not requiring extreme pressure or tightness of the flange and sleeve for retaining the wheel in place. Others provide a series of spots of soft metal having the same object as the soft metal lining. Still others have a plain cast iron surface which is more frequently employed on large hole wheels, as the point of resistance to slippage of wheels in the flanges is brought more closely to the point where the grinding wheel comes in contact with the work being ground. Therefore, the force required to hold the wheel in place is very much less than in the smaller diameter of holes where the gripping medium is farther away from the point of grinding. Other types of mountings require the use of a gasket between the flanges, wheel sleeve and wheel.

In any event, there are certain conditions to be observed in placing a wheel on the wheel sleeve. The more important ones are outlined below:

(1) In mounting the wheel on the sleeve be sure that the wheel slides freely over the center of the wheel mounting. Never put the wheel on when it is necessary to force it on or pound it in place. A slight amount of scraping in the case of a lead center will make a wheel go on freely, or a little rubbing with a rat-tail coarse file in the hole of the wheel having no lead mounting will make the wheel slide on freely.

If the wheel is forced into the mounting when the hole is too small, strains are set up in the wheel, which when clamped by the flanges or the pressure of grinding are apt to cause breakage of the wheel.

(2) Never mount a wheel when the hole is so large that it can shuck about, because such a wheel with a large hole will be very much out of balance and the space left by the opening will make a bridge of the wheel, so that when the wheel is worn down to a point coming close to the diameter of the hole, the pressure from grinding will be sufficient to crack the wheel across this bridge. A wheel mounted in this condition is more apt to slip around than a wheel which fits properly on the center.

(3) Always tighten the wheel sleeve and flanges snugly, especially where the soft metal gasket or blotter is employed, because such holding mediums require a little more pressure to properly mount the wheel and prevent it from slipping on the sleeve. It is difficult to grind pieces round or to size if there is the slightest slippage of the wheel in the mounting.

(4) Do not tighten the wheel sleeve too tightly, particularly where the cast iron or wheel sleeve and flange comes directly in contact with the wheel, without any equalizing medium in the form of soft metal or blotter between them. Too great pressure is sufficient to set up strains in the wheel, particularly where the surfaces are not perfectly parallel, and the wheel, under the pressure of the grinding operation, will explode or fly to pieces.

(5) Always tap the wheel lightly with a hammer or piece of steel after the sleeve has been drawn up on it properly, ready for placing on the machine, to determine if the wheel by such an operation may have become damaged or broken. A small crack may not be readily seen but can be detected if the wheel is struck lightly with a hammer, for a wheel showing such a crack will not ring clearly, whereas a perfect wheel, or one without cracks at all, will.

(6) Make certain that there are no small pieces of foreign substance, such as steel chips, little pieces of brass, dirt, etc., on the surface of the wheel to be clamped by the flanges and sleeve. Such foreign substances are very apt to set up strains in the wheel which will cause breakage if allowed to remain.

(7) Always inspect a wheel by looking it over carefully and tapping it lightly with a hammer before attempting to put it on the sleeve at all. It sometimes happens that wheels are broken or damaged in transit.

J. W. Gerard had a happy way in Berlin of chafing the great war lords and dictators. A grand duke said to the Ambassador at a reception:

"Germany will win this war. Then let America look out."

"How will Germany win?" said Mr. Gerard, calmly.

"With her submarines, with her gases, and, above all," said the grand duke, "with perseverance. Perseverance, Mr. Ambassador, always conquers."

"Always," said Mr. Gerard, winking at a fellow countryman. "How about the hen on the china egg?"

# PROGRESS IN NEW EQUIPMENT

There is Here Provided in Compact Form a Monthly Compendium of Shipbuilding and Marine Engineering Auxiliary Product Achievement

## 26-IN. CRANK SHAPER

MODERN conditions calling for extreme accuracy at the highest speeds and feeds have caused increased attention to be given to shaping-machine design, the continuous and rapid development of this type of machine in recent years having resulted in machines in which workmanship, material and design are equal to that called for in the best tools of other types.

The machine illustrated herewith is of massive construction and capable of affording maximum rigidity under heaviest cuts, and is a recent product of the Canada Machinery Corporation, Ltd., Galt, Ont. It has a maximum stroke of ram of 26½ in. with a cross table travel of 30 in., and vise capacity of 15 in. between jaws.

Column is a single cored casting of exceptional weight, having all bearings cast integral; the bull gear bearing has an enlarged diameter next to the gear, thereby increasing the bearing surface and adding strength at the point under most severe strain. The base to which the column is bolted is deep and well ribbed, and is provided with a front extension having a planed surface for holding table support, and has flanged sides to collect the oil and chips.

Ram has exceptionally large square sides fitted with adjustable gibs, which can be adjusted to take up the unequal wear of ram slide. An improved design of tool head is employed, having both automatic and hand feed which can be set to feed either up or down at any angle. Swivel is graduated to 90 degs. right and left, and vertical feed screw has micrometer index collars graduated in sixteenths and thousandths.

Nine changes of down feed are obtained by means of simple mechanism without moving the dog on the column, and the feed can be instantly stopped or reversed by a convenient crank handle. An automatic throw-out disconnects the feed in case of over-travel of ram and friction washers are provided which slip if the tool sticks.

Three sides of the box form table are machined and fitted with tee-slots. Horizontal travel is 30-in., vertical adjustment 14 in., while table top is 17 in. wide by 24 in. long. The apron to which the table is bolted is provided with tee-slots so that work can be bolted direct when the table is removed. The table support on the outer end of base relieves the cross rail of considerable strain and prevents springing of the table.

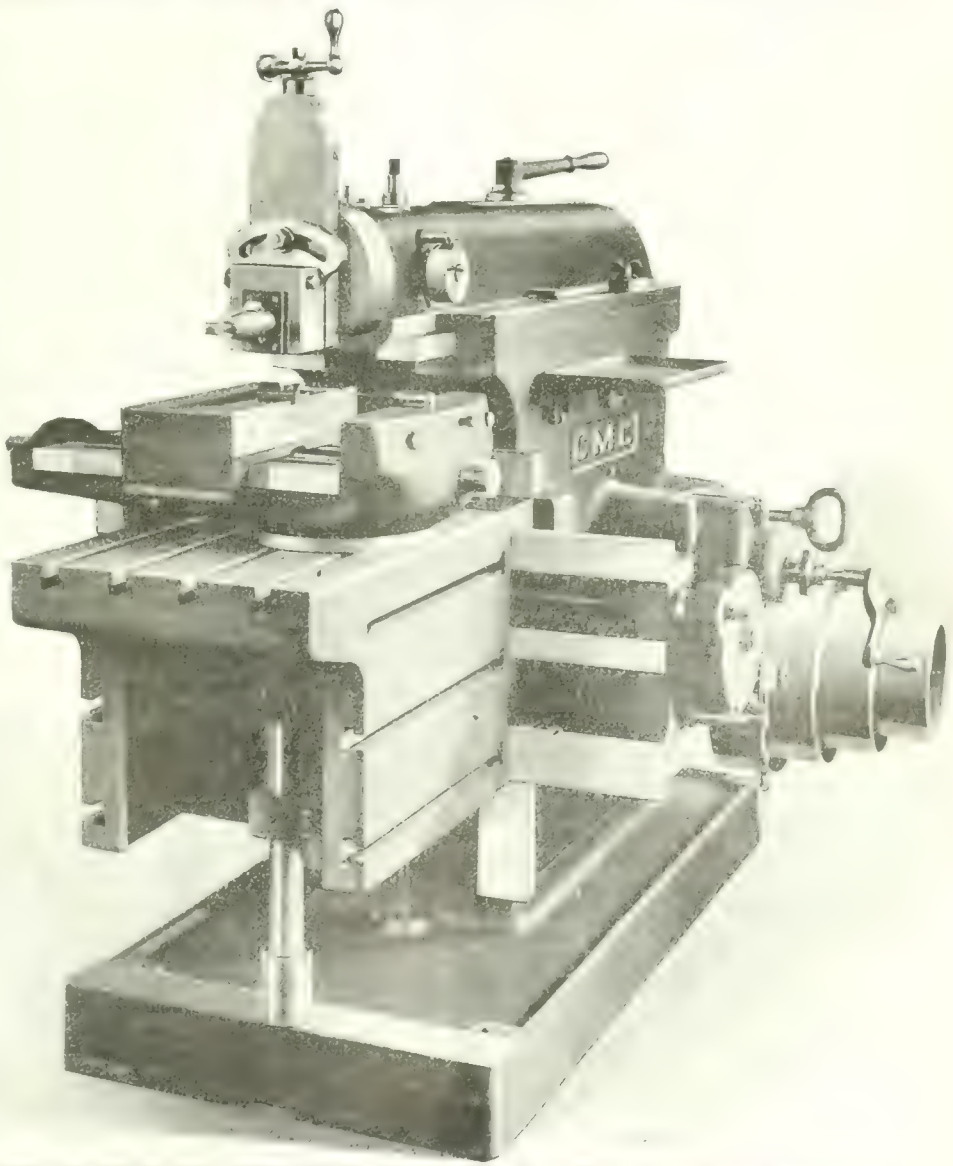
The vise is bolted directly to the table permitting work which projects over the side of the table to be held in the vise, an advantage over a vise mounted on a base.

The cross rail has three bearing faces, the apron being gibbed to the upper and lower faces which are close together.

Drive is by four step cone, provided with double back gears giving ratios of 6 to 1 and 29 to 1, giving 8 cutting speeds on the ram. The rocker arm is attached to the ram by means of a double link which insures an even motion and also eliminates the tendency of the rocker to lift the ram at the beginning of the stroke, neutralizing the upward thrust of the tool.

The eight speeds provided give a range of from 6 to 98 strokes per min. to the ram, the length of stroke being changeable while the machine is running. A direct reading stroke indicator shows the actual stroke the machine is set for, whether in operation or not, and is not dependent on the movement of the arm.

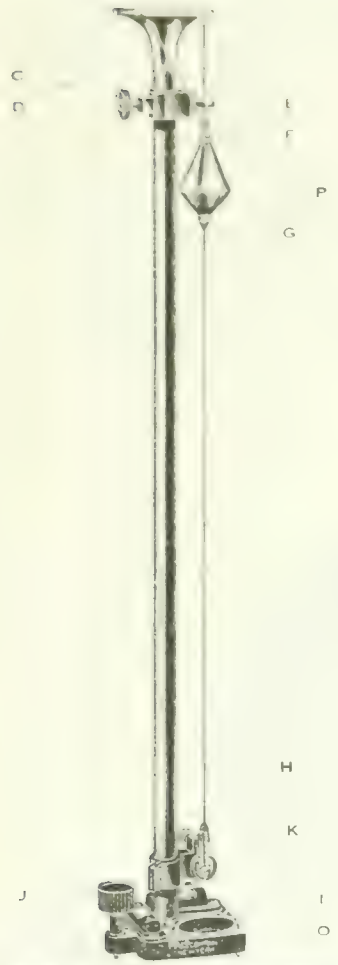
The design of the machine enables a four speed gear box with single pulley or motor drive to be substituted when desired; standard equipment furnished includes vise, swivel jaws, countershaft and full set of handles and wrenches. The weight of the machine is 4,900 lbs.



26-in. CRANK SHAPER WITH POWER DOWN-FEED, DIRECT READING RAM INDICATOR AND SPECIAL BASE SUPPORT FOR WORK TABLE

## A PORTABLE HARDNESS TESTER

INSTRUMENTS for testing the hardness of metal by actual deformation of the surface of the test piece are usually limited to laboratory installations and are heavy. The Waldo hardness tester as supplied by the Palo Company of New York, is unique in this respect, that it is portable and it is claimed still secures



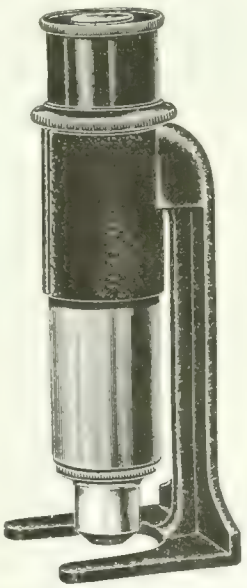
PORTABLE HARDNESS TESTER

weighing one-tenth or one pound, and falling one foot to the surface of the material whose hardness is to be measure This plummet P shown in illustration has a conical, replaceable, chill-tempered, 60 degree, steel point G, of which several are furnished with each instrument. This plummet has tried to its upper extremity a very thin silk thread which bends over a funnel-shaped end piece A,B,C, into which, at A and B, slotted holes are cut with burnished edges so that the silk thread passes through them with practically no friction loss. The funnel A, B, C, turns with a slight friction in the end of the jointed supporting brass tube I, C. The silk thread is attached to a small burnished ring at its lower end, which ring in turn is caught in a little trigger at K, which can be released by the thumb screw H without jarring the instrument. The silk thread then passes from the release catch K through the hole A, through B, through an adjustable third hole at E, which is clamped in place by the thumb screw D so that the plummet point G is exactly over the aperture O in the base of the instrument.

The base of the instrument is supported on three points, two of which are controlled by levelling screw J. Small cross levels indicate the verticality of the supporting rod I, C.

In use, the instrument is set on the surface of the material whose hardness is to be tested, so that the aperture in its base O is concentric with the exact spot to be tested. The plummet is then hung as shown, and lowered by holding the silk thread by its ring between the fingers so that the exact position of the clamp D,E, may be found for insuring the vertical fall of the plummet. This being determined, with the instrument levelled, the thread ring is placed in its releasing trigger K, and with the plummet in its position F, G, the funnel support A, B, is gently turned until the distance from the conical point G to the surface of the material to be tested O, is exactly one foot. The instrument is now ready for use.

A convenient way of stopping any slight swinging motion of the conical point G is to touch it gently with a small camel's hair brush or a piece of cotton wool. The instant the plummet is still, the trigger is released by the thumbscrew H, and the plummet falls, making a uniform circular indentation in the material tested. The object in releasing the plummet from the bottom of the apparatus is to avoid any disturbance in its upper support. The entire operation consumes but a few seconds after a slight experience with the instrument. The microscope is designed so that it has sufficient illumination and magnifying power to measure easily with an eyepiece micrometer the diameter of the impression made by the falling plummet point. The average diameter of the circular depression is then measured. Scale for measuring indentations is embodied in the microscope.

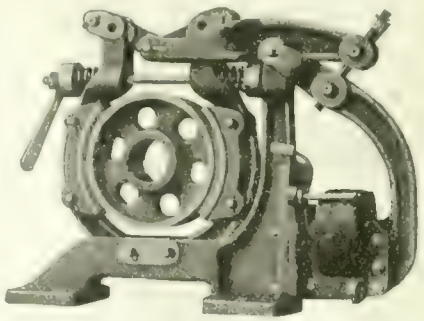


MICROSCOPE FOR USE WITH HARDNESS TESTER.

## MAGNETIC BRAKES

A NEW design of direct current magnet brake has been developed for use with mill, crane and hoist motions. As shown in the accompanying illustration the magnet armature is of the clapper type which eliminates the necessity of having any moving parts within the coil and consequently ensures freedom from wear, sticking or damage to the insulation of the coil windings.

These brakes are characterized by the quickness of their operation. They respond almost instantly, "releasing" when the power is applied and "setting" when the power is cut off. This is due to the design of the operating magnet which gives high initial pull and a very small distance of travel (¼ inch to 1 inch).



MAGNETIC BRAKE FOR USE WITH MILL, CRANE AND HOIST MOTIONS

The operating of the brakes is as follows:

When voltage is impressed on the motor the magnet is energized and the magnet armature lever overcomes the pressure of the compression springs through a toggle and releases the brake-shoe grip upon brake wheel. While the magnet remains energized the brake wheel is allowed to rotate freely. As soon as the current is shut off from the motor the brake magnet releases and the compression springs force the shoes against the brake wheel and bring the motor quickly and smoothly to rest without shock or jar. The compression exerted by the springs can be easily adjusted so that any holding or retarding torque up to the full capacity of the brake can be obtained for equal braking effort for both directions of rotation. Simple means for making adjustment for shoe wear are provided.

In case adjustments for shoe wear should be neglected a safety feature has been introduced so that the brake does not fail to hold the load but the magnet will not release the grip on the brake wheel. This insures proper brake operation and the elimination of accidents due to the slippage of the brake-wheel.

As a product of the Westinghouse Electric and Mfg. Co. the new brake shows in design a close adherence to their alternating current type of brake except in the necessary alterations in magnet and armature lever but the features of simplicity and accessibility of the few parts are typical of both types.

## PUBLICITY AND ITS INFLUENCE ON NATIONAL EFFICIENCY

THE increasing hope which is being placed by the Allies in the ultimate influence of aerial conflict as one of the deciding factors of the war has resulted in growing interest being taken by all sections of the community in the immense aviation program of the United States and the methods adopted by them for insuring the successful carrying out of their plans

Foremost among these plans, and, from an engineers' point of view, possibly the most vital in its ultimate effect on the efficiency of the air service was the decision of the United States authorities to build a standard motor.

On first thoughts the decision to make a standard motor seems to smack of tameness and simplicity, monotony of performance and limitation of power, lack of improvement and a general marking time of all those features whose continued development and maintenance at maximum efficiency is vital at this time.

The conditions under which the engine was evolved are now past history in the technical press, but so accustomed has a certain section of the scientific and engineering public become to accomplishments of this nature that the circumstances attending the inception of the idea were soon dismissed to give place to the more urgent problems of production.

It is more than interesting, however, to consider the real facts as they have come to light as to how a government department could be prevailed upon to take such a sweeping step and do that which, while obvious to many thoughtful students of the situation, was radical enough to make them keep their opinions to themselves. The question of a standard engine? Why, was it not more than Britain had dared to tackle, and did not Britain know best? Why, therefore, should they agitate for a reform, which while desirable from many points of view was still looked askance at by one of the principal belligerents?

In aviation, as in munitions, ships, artillery, etc., it becomes more obvious every day that standardization is the one hope of victory. Why, therefore, was the matter not appreciated much sooner?

An English authority writing to a leading paper on the subject, says: "It is, moreover, known generally that after trying every variety of type in the designs of internal-combustion engines for aeroplanes, the Germans in the Gotha and other machines on which they mainly depend have deliberately chosen and are consistently sticking to vertical cylinder machines, embodying the best verified racing car practice and presenting the most straightforward manufacturing job."

The most straightforward manufacturing job! There is the whole situation in a sentence, and that, with its resulting effects on fighting efficiency—reduction in number of spare parts, simplicity and ruggedness of design, making failure less possible and repair more easy—is the feature of the situation whose importance was recognized by the manager of a leading United States journal in the automobile field.

Soon after the war broke out this publisher sent a writer to Europe who wrote a series of articles on transportation and aviation conditions. Chief amongst his communications were those relating to the many makes and designs of aeroplane motors with no form of standardization among them, resulting in conditions that made for anything but the best results in building and repairing.

The secretary of the Associated Business Papers, Inc., recently reviewed the work of that organization—how its members had been instrumental in adding 8,000 men to the New York State National Guard, and in organizing several engineering and roads units, etc. Further, when the War Department at Washington was able to obtain the services of only four expert mechanical designers, this association and its members were instrumental in raising from among the readers of their papers a force of 104 expert engineers to serve the government.

Confronted with two such evidences of trade paper accomplishment—an expert analysis of fateful conditions with common-sense recommendations regarding the only remedy on the one hand, and convincing evidence of the influential support given such papers by industrial and technical leaders throughout the country on the other hand—was the War Department prepared to go its own way and ignore the obvious?

In Canada, technical journals as a class have not been appreciated at their true worth by the authorities as a means of helping production and disseminating information. Students of the situation find it difficult indeed to account for such a divergence of attitude between two government bodies such as are at Ottawa and Washington. Proximity of location and assumed similarity of thought are without corresponding influence on matters of publicity, and in a smaller community,—less infested, if at all by enemy agents, which has suffered proportionately little material damage from such sources and that entirely unrelated to technical publicity—business papers as a class have not been utilized in the same manner which has yielded such surprising and encouraging results a few short hundreds of miles away.

The ultra-conservatism of British government circles may induce such an attitude on the part of those in authority here, but until they can produce results equaling in importance those obtained by our big ally on the south under a directly opposite policy we shall remain unconvinced regarding the efficiency of their methods.

# Steel Manufacturers to Increase Production 20 Per Cent.

*Government Assistance to Steel Makers Proposed—Coal Shortage Continues Despite Less Severe Weather—Steel Plate Prices Decline—Machine Tool Market Steady.*

**Although the very severe weather has passed, its effect is still being felt in industrial circles more particularly on account of the continued freight congestion. The lack of adequate transportation facilities aggravated by the severe climatic conditions has increased the already acute shortage of raw materials. It will be some time before the industrial situation is normal notwithstanding the efforts that are being made to ameliorate conditions. The coal shortage is particularly acute and the shortage of cars appears to be the primary reason. For the same reason there is a shortage of coke which is curtailing the output of iron and steel. On account of the serious shortage of steel, the steel manufacturers have agreed to increase production by 20 per cent. over the 1917 output, providing adequate supplies of raw materials are available. The Dominion Government proposes to assist the steel men in the attainment of this object. If the mills are able to increase production to this extent, the shortage will be materially relieved in so far as certain products are concerned. The outlook in regard to steel products imported from the States, however, is not so hopeful. Prices of steel plates, black and galvanized sheets and Canada plates have declined due to the lower prices on these products prevailing in the States. Prices of all other steel products are firm and unchanged. There has been a general advance in the prices of lubricating oils and compounds, ranging from 3c to 8c per gallon. Copper, antimony and aluminum are weaker and quotations lower. There is no improvement in the tin situation which continues acute. The machine tool market continues steady**

MONTREAL, Que., Jan. 21, 1918.—Coal conservation and the drastic measures taken by the American Fuel Controller to rectify the difficulties that are so emphasized at the present time are the central features in a situation that is marked with questions of vital importance to the industrial and commercial activity of the United States and likewise Canada. This action on the part of the American Government was so sudden that very few of those affected were prepared for the sweeping regulations and restriction of production that the measure entailed. However, it appears that fewer industries will be severely affected than at first supposed, and it will likely be only the non-essentials that will be materially restricted, although a large number of manufacturing plants and domestic interests will be required to observe the ruling that has been put into effect. The primary reason for this drastic order was to conserve the available supply of fuel and regulate its distribution to such industries as are essential to the immediate prosecution of the war; a factor that was considered of primary importance. While the observance of this impromptu law is only intended for the United States, its effect will be far-reaching and Canada must sooner or later realize the important bearing that such action must have on this country. Railroad transportation is again resuming its normal activity after the severe trials of the past few weeks, but many districts are still laboring under the excess freight that has accumulated during this period.

### Pig Iron

The production of pig iron has been greatly affected by the disturbing conditions [illegible] as regards the weather and also the political situation. Furnaces have suffered much from the lack of coke and other raw materials [illegible] of a very poor grade, so that producers [illegible] meet the heavy demands of steel making requirements. Negotiations are still on between the Canadian and American Governments to see what arrangements can be made to obtain delivery of more pig from American sources, but so far nothing satisfactory has been done. Little Canadian metal is for sale, and producers report a situation that is becoming increasingly acute. Prices are nominal, with virtually no quotations.

### Steel

The drastic measures recently taken by the American Government for the conservation of fuel has marked an epoch in war-time developments. Following the period of demoralization of trade incidental to the severe weather that has prevailed in all sections of the country, this latest action on the part of the United States authorities has added to the disorganization of the steel industry. The measure that was primarily thought to include all manufacturing industries has, however, been shorn of its severity, as more recent announcements appear to indicate that many of the more essential manufacturing establishments will be allowed to continue their activities provided sufficient supply of fuel is now available. Much dissatisfaction has been openly expressed at the ruling of the American Fuel Controller, but on deliberation it may be found that such a policy is in strict accord with the requirements of the country, as conditions at the present time make it imperative that the distribution of fuel should be so regulated as to cause the minimum inconvenience to all concerned. The congestion of supplies for export that is becoming more and more pronounced every day on the Atlantic seaboard will be relieved by the shutting down of additional arrivals, and during the interval of inactivity of manufacturing it is hoped that the coaling and loading of bottoms will enable shipping to become less acute at these ports of distribution. The movement of freight that has been curtailed during the past few weeks has resulted in the accumulation of excessive supplies at the mills and foundries, so that warehouses are filled to capacity and embargoes add to the difficulty of clearing and shipment of material.

The possible diversion of coal and coke to more essential industries threatens to disorganize many merchant furnaces and other domestic activity. Steel production has been so hit that it has been estimated that during the past two weeks the output has been about 50 per cent. below normal. Conditions during the past few days have shown much improvement and the transportation companies are in a better position to handle the enormous quantities of freight that has been piling up since the bad weather set in. With a good spell of moderate weather it is hoped that the situation in the near future may take on a much easier tone. While Canadian activities are not directly reflected in the disturbed condition existing in the States, the situation here is marked with considerable nervousness over the recent developments. While Canada as yet has not felt the actual pinch of coal shortage, the scarcity is none the less apparent, and the future has not been improved by the developments across the line, as Canada, to say the least, must share the burden equally with her Southern neighbor, particularly with that portion of fuel that is brought in from the United States. Local conditions are comparatively unchanged with the inability to obtain material particularly pronounced; price quotations are relatively the same and very firm.

### Metals

Apart from the slight excitement that has developed through the increase announced in the price of lead, the situation is devoid of any feature of consequence. Copper is regular and unchanged. Tin is uncertain, with arrivals just sufficient to meet the most urgent requirements. Interest in spelter has

been renewed by the announcement that a fixed price may soon be made. Lead is not active, but the market is stronger. Antimony and aluminum are both firm and unchanged.

**Copper.**—While some agitation has been made for an increase in the fixed price on copper, it is very unlikely that such action will be taken owing to the apparent satisfactory situation that now prevails in this market. Nothing has developed that would indicate that the American Government are contemplating a further revision of copper prices, at least in the immediate future. Refineries have suffered by the recent tie-up of railroads, but not to the extent of other industries, owing to the fact that their fuel supply was ample to carry them over the acute period. The local situation is much the same as last week, with business steady and comparatively brisk. Prices are unchanged at 32c and 33c per lb.

**Tin.**—Consumers are beginning to realize that the metal at any price is of more importance than the price itself, and are, therefore, booking in advance, irrespective of what the future may develop. The situation in the States is comparatively unchanged, with shipments arriving fairly regularly. Permits are still difficult to obtain, but sufficient metal is coming through to avoid undue nervousness, but the inability to obtain enough to acquire a surplus supply has the tendency to retain the market in a very strong but uncertain position. New York quotations are still nominal, and dealers here report a strong and steady market, with an undertone of strength. Current quotations are strong and firm at 77c per lb.

**Spelter.**—After several months of investigation and negotiation it is reported that the American Government are about to fix the price on grade "A" spelter. Just what this price will be is uncertain, but leading producers anticipate that a fair price would be about 12c or 13c per lb. For the past few months sales made on Government requirements have been made on the understanding that a price would be decided on and settlement made on this adjusted or agreed figure. Apart from the expectancy of the Government action the market is unsettled and quiet. The local situation is dull and quotations are unchanged at 10½c per lb.

**Lead.**—Despite the fact that the demand has not been such as to justify an advance, the Trust price on lead has again been advanced ¼c per lb. This makes the ruling quotation on the New York market 6¾c per lb. Speculation appears to be the cause of this most recent development, as producers are not selling and consumers show no disposition to buy other than for their immediate requirements. The demand on the local market continues light, and dealers report unchanged prices, but with an undertone of strength; present quotations are on the basis of 9¾c per lb.

**Antimony.**—Slight activity was evident in this market during the past week, but buying was light. The market generally has a tone of weakness, but quotations continue firm. Locally the situation has developed no features, and quotations remain unchanged at 18c per lb.

**Aluminum.**—Nothing of importance to report in this market, and quotations are comparatively unchanged, slight declines being noted on the New York prices. Dealers here continue to ask 60c per lb.

### Machine Tools and Supplies

While the activity in the machine tool industry shows little improvement over that of the previous week the outlook seems to be very encouraging owing to the satisfactory inquiries from many sources. The demands for munitions equipment continue light, although some purchases have been made to supplement plant equipment already in use. Business in general machine shop tools is of a steady character, but delivery has been very poor owing to the difficulties of transportation and the shortage of cars on the various railroads. The volume of business in the United States in connection with war requirements is so enormous and the urgency so imperative that shipment of tools to Canada from American builders is next to impossible. At present the local activity is confined to light buying of such equipment as would be required for general purposes. The demands for all classes of supplies, both as regards small tools and machine shop accessories, continue on scale equal to the industrial activity of the country, but in common with all other commodities the delay in delivery causes no small inconvenience to many manufacturers. High speed steel is in good demand, but is often difficult to obtain owing to the inability to secure shipment of material from England and the abnormal consumption in the States. Prices on all small supplies are well maintained, and the market is generally firm.

### Scrap

The market has again taken on a better tone and activity has increased following the period of dullness incidental to the railroad difficulties resulting from the severe weather of the past few weeks. Local business is far from brisk, and dealers here are watching the American market for developments. Generally the situation here is unchanged, with slight fluctuations reported during the past week, but current quotations are on a par with those listed last week. New York reports a decline on copper and brass scrap and a corresponding advance on lead.

**CANADIAN GOVERNMENT PURCHASING COMMISSION**

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

## Toronto

TORONTO, Ont., Jan. 22.—The drastic order issued by Fuel Administrator Garfield suspending manufacturing operations for five days in all States east of the Mississippi River caused a sensation in local industrial circles on account of the possibility of a similar order being enforced in Canada. There has been no hint given out that such drastic measures are contemplated but the coal situation is sufficiently severe to warrant unusual methods being adopted to relieve the congestion on the railways. Latest reports indicate that coal is moving in heavier volume but there is a considerable deficiency to make up before the situation is anything approaching normal.

### Steel

As a result of a conference held at Ottawa between the war Committee of the Cabinet and the steel manufacturers it was announced a few days ago, that the manufacturers have undertaken to increase the production of steel 20 per cent. over last year provided sufficient supplies of raw materials are available. The key to the situation is raw materials and it is here where the government will have to take a hand in relieving the present congested condition on the railways and also assist in providing additional labor of which there is a shortage. Unless sufficient supplies of raw materials can be obtained, the steel men cannot increase production. The railways are badly in need of rails and the mills at the Soo and Sydney will be called upon to furnish the required tonnage. It is understood that the U.S. Steel Corporation has sold to a Canadian interest 2,500 tons of rail at a price above $57 per ton. A twenty per cent. increase is a fairly tall order for the steel production last year was larger than any previous year. The steel companies have for some time been extending their plants and generally increasing their all round efficiency so there should not be much difficulty in obtaining the required increase in output, providing of course that the necessary raw materials are available.

This new arrangement should go a long way towards relieving the shortage of steel, although on steel products imported from the United States, Canadian consumers will still be dependent upon the mills across the line. In view of conditions in the trade in the States and the enormous demand for steel there appears to be little hope of any material increase in the available supply for consumers in Canada. According to the latest information there is no lack of steel in the States for government work but manufacturing consumers not engaged upon

per cent. capacity. The situation in the [illegible] is serious and will affect consumers in Canada. The U.S. Government, however, is endeavoring to relieve conditions and it [illegible] there is a considerable improvement in the situation.

There has been a downward readjustment in prices of steel plates and black [illegible] Canadian market, as a result of the lower prices obtaining in the States. Warehouse prices in the States are still below prices in Canada because the former benefit by the lower mill prices, these being fixed some time ago. Canadian consumers on the other hand do not necessarily benefit by the fixed price schedule, so prices here are not always based on those prevailing in the States as was the case at one time. There has been no change in Canadian mill prices and there is no indication of a movement either up or down. There is no change in the steel plate situation. Although prices are down it cannot be said that the decline indicates weakness in the market. Every ton of plate produced is required.

Plates ¼ in. and heavier are now quoted at $10; heads $10.30 and tank plates $10.10 per 100 lbs. Black sheets No. 28 gauge are now quoted at $8.25 and No. 10 gauge $10 per 100 lbs. Galvanized sheets are likewise down, Premier No. 28 U.S. being now $9.20 and 10¾ oz. $9.50. Canada plates dull, 52 sheets, are now quoted at $8.50 and all bright $10 per box. Prices of all others steel products are firm and unchanged.

### Pig Iron

The pig iron situation continues acute and there is no improvement in conditions in the trade. Although the effects of the storm last week are diminishing, the weather continues cold handicapping the railways in their efforts to move freight. A decline in production at the ovens and freight congestion have both reduced available supplies of coke with the result that the shortage is greater than ever. There is no free coke in the open market and it will likely be some time before there is any, the requirements of contracts being quite in excess of production.

### Scrap

[illegible] very quiet, there is very little business being done. The freight congestion is partly responsible for this condition but there is also little enquiry for old metals, except perhaps heavy melting steel and cast iron scrap which are in fair demand. There have been no price

### Machine Tools

Business in machine tools continues on a steady basis, the demand being largely for equipment for munitions plants. Canadian machine tool builders are keeping busy, particularly for special tools for munitions plants. The machine tool trade in the States is very active and many lines are hard to obtain. Deliveries continue to get more backward and shipments are being delayed owing to the congestion of freight.

### Supplies

There has been a sharp advance in oils and compounds and new prices have been named for the following: machine oil 29½c; cylinder oil, capital 49½c; cylinder oil, acme, 41½c; lard oil, $2.55; Imperial quenching oil 4½c per gallon. Standard cutting compound is now quoted at 7c per lb. and acme cutting oil, antiseptic, 39½c per gallon.

### Metals

There is a weaker tendency in prices of non-ferrous metals this week due for the most part to local conditions which have resulted in declines in copper, antimony and aluminum. The decline in copper is partly due to the fact that prices are fixed in the States but a slight scarcity of the red metal has had the effect of keeping prices up locally. Although the price of copper has been fixed at 23½c there is some possibility that this may be raised to 25c. There is no improvement in the tin situation and quotations continue nominal. No tin is allowed to leave England where a considerable tonnage is being held up. Both lead and spelter are firm at unchanged prices. Business in this district in the metal trade continues satisfactory.

**Copper.**—Although the price of copper was fixed at 23½c, an effort is being made to raise the price to 25c. It is not only the small producers that are behind the agitation but some of the larger producers are also urging upon the U.S. Government to change the maximum price to 25c. The producers claim that a higher price is necessary to make a reasonable profit in view of the all round increase in producing costs. Some of the larger producers are satisfied with the Government price but admit that production may be slightly curtailed at the present price which might be increased to 25c. There is a slight weakness in copper locally, prices having declined on cent. Lake and electrolytic are quoted at 31c and castings at 30c per pound.

**Tin.**—The tin situation continues to grow more serious and prices are entirely nominal. There is no spot tin available in New York and no metal is allowed to be shipped from England. Permits are so uncertain that the trade does not know when any more tin will be shipped or in what quantiy. Locally the quotation is entirely nominal at 80c per pound.

**Spelter.**—The market has a stronger tone notwithstanding that the available supply is more than ample to meet current consumption. The government purchases are likely the reason for the improvement in the situation. Local price is unchanged at 10½c per pound.

**Lead.**—The position of lead is more satisfactory and the supply so far has been sufficient to meet consumers' trade The undertone of the market is strong with an upward tendency, though it is not thought probable that there will be any sharp fluctuations. Local price 9c per pound.

**Antimony.**—The market is weaker and the price of antimony has declined 1c. The demand at the present time is very light. Antimony is now quoted at 17c per pound.

**Aluminum.**—Lack of demand and a weak market has resulted in lower prices for aluminum which is now quoted at 60c per pound, a decline of 2c a pound.

## New York

NEW YORK, Jan. 19.—A sudden and urgent call for 1,000 machine tools has come from the Ordnance Dep't. of the Army through the machinery section of the War Industries Board. The machinery is required for the manufacture of big guns and unless the tools are delivered within sixty days the program of the Government for producing ordnance will be seriously disarranged. Some of the tools are wanted within thirty days. The list includes 500 planers, a number of horizontal milling machines, a large number of vertical milling machines, several hundred engine lathes and over 100 floor type horizontal boring, milling and drilling machines. Builders of and dealers in machine tools are unable to meet the Government demand and a hurry call has been sent broadcast through the industrial press to all manufacturing industries having tools not engaged on war work. The Government is ready to buy, rent or to borrow any tools that will meet the requirements. The American army in France must be provided speedily with heavy guns and unless this ordnance is supplied mortality among the troops will be increased enormously; a strong appeal is therefore made to the patriotism of manufacturers who may have tools of the type needed by the Government to release them for use in the manufacture of ordnance.

### Increased Rifle Output

The Navy Dep't. has distributed orders for 60 locomotive cranes. The Frankford Arsenal has also made additional purchases of machinery and manufacturers in the Central West who have received contracts for war munitions are buying shop equipment. The Winslow Ornamental Iron Works, Chicago, has placed orders with the Amalgamated Machinery Corp., which will be used in executing a contract for 200,000, 155 mm. shells, corresponding to United States 6-inch shells. The capacity of the Remington plant at Eddystone, Pa., is being increased and new equipment is being purchased. When the improvements are completed the plant will be able to turn out Enfield rifles at the rate of 6,000 per

day; its present capacity is 2,500 per day. The Hyatt Roller Bearing Co., Newark, N.Y., which has a contract to manufacture 1-pound shells for the United States Government, and the Regina Co., Rahway, N.Y., which is to manufacture roller bearings for war munitions are now in the New York market for shop equipment. The S. K. F. Ball Bearing Co. of Hartford, Con., has bought tools recently for installation in an extension to its plant. Several other New England manufacturers holding war contracts have placed orders for plant additions which will require purchases of machinery.

### Cantonment Shops

An interesting report is that the Government will install machine shops at all of the cantonments to develop a corps of machinists that will be ready to make repairs to field equipment in France. Machine shop equipment is also to be purchased for the American armies in the Phillipines and in Hawaii.

Manufacturing industries throughout the country were startled by the sudden order issued by the Fuel Administrator to shut down all plants for five days beginning with Jan. 18 and on all Mondays up to March 25. It is evident that the action of the Fuel Dep't. was as much to assist in relieving freight congestion as it was to save fuel. The order exempted blast furnaces, coke ovens, and steel mills rolling products required by ship yards and by manufacturers of war munitions. The original order was also modified to permit the operation of copper refineries and of several other plants, the output of which is essential to the manufacture of important war munitions. Previous to this order, however, the lack of fuel, heavy storms and low temperature had caused further reduction in operations of blast furnaces and of steel plants. The industry as a whole to-day is operating at scarcely 50 per cent. of capacity. Prostration was greatest at Chicago, and industrial activity there to-day is scarcely more than 30 per cent. of capacity.

## Pittsburgh

PITTSBURGH, Pa., Jan. 19.—All ordinary consideration as to market activities and trade prospects yield at the moment to the immediate influence and probable effect of the Fuel Administration's drastic plant-closing order. Fuel is not to be burned for operating plants from Friday, Jan. 18, to Tuesday, Jan. 22, both dates inclusive, also for the Mondays to and including Mar. 25. As to the ten Mondays involved other interests are included, office buildings and newspapers among others, newspapers being limited to one edition.

Perhaps naturally, there was a great deal of criticism in various quarters when the order was suddenly announced. This report need not concern itself with the causes for the order being issued or with the criticism, for this is intended to be an iron and steel report, and the outstanding fact is that the iron and steel industry has not criticised the order. Some iron and steel men have made criticisms, but the criticisms have been of those who criticized the order and the Fuel Administration. Promptly upon hearing of the order the iron and steel industry decided to obey it promptly and to the letter.

### The Exemptions

To desire to obey, and to obey, were two different things, however. The major portion of the capacity was closed Thursday midnight, while departments that were running after that hour were closed as rapidly as it was physically possible. Then exemptions began to be received by wire from Washington, and various departments were put in operation again as rapidly as possible. By Friday night partial or entire exemptions had been received by steel companies that produce altogether at least 80 per cent. of the country's steel, but the proportion of their capacity that they were expected to operate could not be estimated very closely. It would probably represent in the aggregate somewhat less than one half their capacity. While some additional exemptions were being ordered hourly to-day, the best estimate seems to be that during the period, embracing four regular working days, about one-half or a trifle less of the steel making and steel finishing capacity is operated.

The exemptions are wholly with respect to the production of material on Government order, but on the one hand they do not cover all war material while on the other hand there is some interlocking, whereby the operation of a department filling war orders may at the same time involve the production of some tonnage of the material.

### No Curtailment of Steel Production

The fact cannot be emphasized too strongly that this plant closing order does not really involve the loss of production of a single ton of steel. Whether the Fuel Administration realized this or not is not known and might not be to the point in any event. It is the actual fact that counts. For perhaps a twelvemonth, and very emphatically in the past few months, the production of steel has hung entirely upon the production of pig iron. In 1916 the country made 39,400,000 tons of pig iron and 41,400,000 tons of steel ingots. In 1916, chiefly the latter portion of the year, and in 1917, there was added steel making capacity rated at over 8,000,000 tons of ingots a year. In December, pig iron production was at the rate of 34,300,000 tons a year and steel ingot production at the rate of 37,200,000 tons a year. The ingot production was easily at 10,000,000 tons less than capacity, but the production was all that could be compassed with the supplies of pig iron and scrap available. The blast furnaces could make no more pig iron because they were not sufficiently supplied with coke. The blast furnaces remain in operation during this five-day period, and they are likely to receive larger rather than smaller supplies of coke by reason of other plants being closed. The pig iron produced will eventually be converted into steel, by reason of the excess capacity available.

### Eventual Gain

One of the objects of the Fuel Administration's order is to get coal through to vessels ready to sail. Another object is to clear the railroad congestion and pave the way for a better traffic movement. If the order accomplishes its purpose a result will be a better movement of coke to blast furnaces, consequently larger production of pig iron and in turn of steel.

The occasion for granting exemption from the closing order to departments making certain descriptions of war material is that these departments have been working at capacity and produce only so much irrespective of the supply of steel, so that their idleness would represent a loss in production of the particular material involved. Thus the first exemption order that reached Pittsburgh referred to the manufacture of seamless drawn steel tubing under 1½ in. dia.

### Other Remedies

The fuel saving order is in addition to other remedies that have been applied to right the industrial situatuion. Every effort is being made to improve conditions on the railroads. The embargoes referred to in last report are continued, preventing the shipment of much of the steel that is produced, the object being to clear the congestion on track. These embargoes, now in force for more than a fortnight, would have produced better results by this time had there not been very untoward weather conditions meanwhile. Originally there had been some hope of lifting them at the present date but all the opinion that railroad officials would vouchsafe early this week was that the embargoes would be continued to next week. In the past fortnight the production of finished steel in the Pittsburgh and valley districts has been little more than one-half the capacity, and the shipments have probably amounted to considerably less than one-half the production. In the past week there has been some curtailment forced through storage room for finished product being completely occupied. As the exception tests the rule, it may be mentioned that of all finishing departments in the general steel industry the tin plate mills probably have the greatest storage facilities, equivalent at the various plants to the storage of the entire output for from five to eight weeks, yet on an average the tin plate mill warehouses are stocked to about two-thirds of capacity, and one large plant, the Farrel works, was closed a week ago as its warehouse was completely full.

### Production and Transportation

Administrator Garfield's statement that the transportation that has been conducted. There is overproduction relative to the facilities that have been available for moving the material.

### INDUSTRIAL BANK SCHEME PROPOSAL

A REPORT has been issued by the Committee on Banking of the British Empire Producers' Organization, London, England, recommending a new scheme for a State-guaranteed bank for the financing of industry.

The general object is to afford readier financial support on sound principles throughout the United Kingdom and the oversea dominions and colonies for producers and manufacturers, and among other results it is intended that there shall thus be in any event no opening for German financial intrigue in obtaining control of any group of industry. It is claimed for the scheme that on the one hand it involves no departure from methods which have been successfully demonstrated on a national scale, and on the other hand it conflicts in no way with the ordinary business of joint stock banks, but is, on the contrary, calculated to increase their turnover.

The available capital would be provided in the shape of debentures and deposits with State guarantee. Further capital would be accumulated by the funding of profits, as apart from a small bonus to debenture-holders and depositors all surplus will remain in the bank. Provision is made for government by boards of trustees, on which both employers and employed would be represented.

It is proposed under this scheme that there should be a guarantee capital of 50 millions sterling, to be enlarged as demand shall arise, and that the guarantors should be:—The United Kingdom, £25.000.000; the Dominion of Canada, £6.000.000; the Commonwealth of Australia, £6.000.000; the Dominion of New Zealand, £2.000.000; the Union of South Africa, £2.000.000; Newfoundland, £1,-000.000; Straits Settlements and Malaya, Ceylon, British Guiana, Mauritius, West Indies, Rhodesia, Falkland Islands, Fiji and other British possessions, £8.000.000.

The declared objects are to strengthen and to extend producing and manufacturing industries already established in the Empire; to assist in the foundation and development of new industries therein; to assist by credit facilities in the sale of their products; to assist them in obtaining materials, machinery, and facilities from other parts of the Empire to those in the countries within the Empire by its citizens of control and utilization of its own products; the foregoing to apply only to companies, firms, and undertakings of British origin and whose registration is within the British Empire.

The Council will carry out the

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE Valparaiso, British Consul General.

COLOMBIA Bogota, British Consul General.

ECUADOR Quito, British Consul General Guayquil, British Consul.

EGYPT Alexandria, British Consul General.

FRANCE Havre, British Consul General Marseilles, British Consul General.

INDIA Calcutta, Director-General of Commercial Intelligence.

ITALY Genoa, British Consul General. Milan, British Consul.

MEXICO Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA Caracas, British Vice-Consul.

BRAZIL Bahia, British Consul. Rio de Janeira, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

### CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Rey, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

### CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum, Grubbegd No. 4 Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

### CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

objects by: Making advances by way of cash credits against such security or guarantee as the trustees shall deem sufficient; accepting drafts made against shipments or deliveries of industrial products or of materials; buying and selling bills of exchange against collateral security; issuing letters of credit; discounting trade bills, purchase of secured time payment accounts or by advances upon the same; to assist and to co-operate with other financial institutions in underwriting the share and debenture issues of present or future industrial undertakings; to collect and collate information likely to be useful to its customers.

## WILL INCREASE STEEL PRODUCTION 20 PER CENT.

AN increase of twenty per cent. in the steel production of Canada over that of last year is promised as the result of conferences held between the War Committee of the Cabinet and the Canadian steel manufacturers. The announcement is one which will, it is thought, be welcome alike to the Imperial Munitions Board and the Canadian railways.

The immense amount of steel required for the manufacture of munitions has prevented the railways from securing rails from the Canadian mills. The output has not been sufficient to meet the requirements of both the munitions manufacturers and the railways, with the result that the latter have stood aside. While in some cases they had contracts with the steel companies for the manufacture of rails, they have waived their claims to permit the fullest possible manufacture of munitions.

The railways, however, could not longer continue in this position. Their maintenance requires a supply of steel rails. It, therefore, became necessary for the Government to deal with the question.

The steel manufacturers were called into conference last week. The leading manufacturers of Canada were present, and the situation was fully explained to them. The manufacturers expressed an earnest desire to co-operate in every possible way, and, after conferring with the War Committee of the Cabinet, they met together and discussed the question of an increased production of steel. As a result of these conferences it is announced that the manufacturers have undertaken to increase the production of steel twenty per cent. over last year, provided the raw materials are available as usual. This decision is a source of considerable satisfaction to the Government since it helps to solve the problem of the steel supply.

## MARKET FOR PUMPS IN PARAGUAY

HENRY H. BALCH, United States consul at Asuncion, reports that there is a good market for small pumps in Paraguay. Inasmuch as there is no water-supply system for the city of Asuncion, which has about 80,000 population, or for any of the other cities or towns of the Republic, there is a constant demand for a limited supply of hand pumps, windmill pumps, electrical, and gas pumps to be used in wells for the purpose of supplying water to residences, business houses, public buildings, etc., in Paraguay. Aside from two breweries, three ice plants, three sugar refineries, some small bottling plants, and a very few other small plants which require pumps a little larger than those used by the average family, there is practically no market for any class except those used in supplying water from wells for ordinary family needs. The total value of all pumps imported into Paraguay in a year averages about $6.000, of which more than half represents imports from the United States. Germany hitherto has been the nearest competitor, followed by England.

**Boston Insulated Wire & Cable Co.** has been incorporated at Ottawa with a capital of $200.000 to manufacture wire and cables used for electrical and other purposes at Hamilton, Ont. The incorporators are: B. T. Burley, of Worcester, Mass.; H. B. Burley, of Brookline, Mass.; and G. W. Arnold, of Hamilton, Ont.

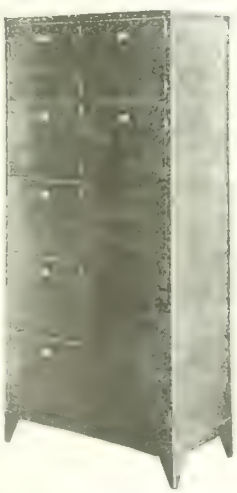
## Six-in-One Combination Locker



The newest idea in space-saving, fire-proof steel ward robe lockers.

Accommodates the clothing of six people in the general coat compartment and gives each a roomy space for hat, lunch box, etc., as shown.

Each private compartment has its own key, but all keys will unlock the larger compartment.

This locker is ideal where space is limited, as it occupies only three feet wide space, whereas single lockers of the same dimensions would take up a space nine feet wide. Identical units may be added as required. Beautifully finished in rich olive green baked-on enamel.

*Write for illustrated folder.*

THE DENNIS WIRE AND IRON WORKS CO. LIMITED

LONDON CANADA

# 35,000 Shells Nosed With One Nosing Die

and the die still working, and apparently good for several thousand more.

Can you beat that record? We know the above statement to be true, for the die is at work in our own shops, and our records prove that it has already nosed 35,000 4.5 H.E. shells. It is still doing good work, satisfactory to the Government inspectors.

This die is made of our special **Chilled Cast Iron**, harder than the best tempered steel on the wearing surface, but soft and tough elsewhere. That is why it wears so well. No other metal possesses this graded hardness of structure. And no other metal, we believe, will resist so well the hard wear and the temperature strains to which a nosing die is subjected.

## ENGINEERING

**Windsor, Ont.**—The plant of the Studebaker Auto Co. has been damaged by fire with a loss of $50,000.

**Hamilton, Ont.**—The Swift Canadian Co. contemplate building a packing house here. Head office Chicago, Ill.

**Dundas, Ont.**—John Bertram & Sons Co. have let practically all the contracts for the new addition which will cost about $150,000.

**Joliette, Que.**—La Compagnie Canadienne de Papeterie which is building a paper mill here will be ready to begin operations shortly.

**Port Arthur, Ont.**—The new plant of the Port Arthur Pulp and Paper Co., with a capacity of 50 tons of pulp daily, is to commence operations in a few days.

**Sydney, N.S.**—The Sydney Foundry & Machine Co. contemplate moving their plant to a new site on the water front. A shipyard will probably be established at the new site.

**Walkerville, Ont.** — The Dominion Stamping Co. has awarded the contract for a forge shop and is in the market for machinery, including drop hammers. The new building and equipment will cost about $16,000.

**Toronto, Ont.**—Fire completely destroyed the Belmont garage, near stop 18, North Toronto, on Thursday morning. The building loss is estimated at $1,500, while motor cars, valued at $7,500, were also destroyed.

**Gowganda, Ont.**—According to latest reports efforts are being made to re finance the South Bay Power Co. and instal a plant at Hanging-Stone Falls. The initial development is understood to be for a unit of 350 h.p., which will be developed from Hanging-Stone Creek.

**Picton, Ont.**—The Town Council recently passed a Hydro enabling by-law. The present lighting plant is steam-operated and is the property of the municipality. It proposed to close down the steam plant and change the distributing system over to suit Hydro current.

**Gananoque, Ont.** — The Gananoque Spring and Axle Co. expect to have their axle-hammer shop in full operation in about ten days' time, as reconstruction necessary after the recent fire will be undertaken immediately the fire loss has been adjusted. The fire will in no way affect the company's spring business.

**Cobalt, Ont.**—Operations are being resumed on the Huronia mine in Gauthier Township. A number of men have left for the mine to commence repairing the mill and pumping out the workings. This mill, and from time to time more or less extensive operations have been carried on and, considering the amount of development work done, satisfactory results were encountered.

## MUNICIPAL

**New Liskeard, Ont.**—The by-law to raise $1,475 for the purchase of road machinery was carried.

**Chatham, Ont.**—Fire Chief Pritchard has recommended that the council purchase a 75-foot aerial truck.

**Ottawa, Ont.**—The ratepayers voted in favor of an expenditure of $150,000 on the proposed St. Patrick street bridge.

**Picton, Ont.**—The municipality propose to instal a motor-operated centrifugal waterworks pump of 1,000 gal. per min. capacity.

**Goderich, Ont.** — The Hydro-Electric Commission has offered to install a new pump at the sub-station here. The existing pump will be sold.

**Fergus, Ont.**—The ratepayers have voted in favor of granting a loan of $10,000 to James Wilson to assist him in rebuilding Monkland Mills.

**Midland, Ont.**—The Water and Light Commission are in the market for a motor-driven pump having a capacity of 1,500 gallons per minute. W. Dudley and A. W. Bell have the matter in hand.

**West Vancouver, B.C.**—The City Council has endorsed the action of North Vancouver City Council and its mayor in urging that a steel plant be established on the Pacific Coast to deal with ores from the province.

**Toronto, Ont.**—Fire Department estimates include an item of $29,400 for a combined hose, chemical and pump motor truck, and $17,000 for an aerial hook and ladder truck. Other new equipment totals $28,153, including equipment for trucks and halls.

**Ottawa, Ont.**—The City Council has adopted the recommendation of the Board of Control that application be made to the Ontario Railway and Municipal Board for leave to borrow $250,000 for the erection of a necessary fuel plant and for the purchase of fuel.

**Wellington, Ont.**—The town has passed enabling money by-laws. It is proposed to issue debentures for the sum of $10,000 for the purpose of buying out the existing lighting system and remodelling it. The Niles estate owners of the existing system has agreed to sell to the town for the sum of $3,000.

**Hamilton, Ont.**—The Board of Control has been informed that T. J. Stewart, M.P., and the local Senators would oppose any application Hamilton would make to the Finance Minister for permission to issue debentures to cover the cost of the new pumps that have been ordered for the waterworks. Mr. Stewart has opposed this scheme, and recently announced that an auxiliary electric supply could be obtained to operate electric units. It was decided to send a deputation to Ottawa to interview the Finance Minister, and ask him to permit the city to issue the debentures.

**London Ont.**—An addition to the hydro-electric power station on York street, to cost about $60,000, will be commenced this year, it was announced at the inaugural meeting of the Public Utlities Commission on Thursday afternoon. Estimates will probably be presented at the next meeting. The Canadian Westinghouse Co., of Hamilton will supply the electrical equipment which will cost $25,400. The present station is overloaded and the addition will provide for handling at least 15,000 more horsepower, making the maximum for the city about 25,000 horsepower.

## BUILDINGS

**Toronto, Ont.**—Permission has been granted by the city architect to the T. Eaton Co. for the erection at 75 Teraulay street of a one-storey brick shipping enclosure to cost $4,000.

**Toronto, Ont.**—The following items have been included in the Board of Education estimates for 1918:—Providing and improving the heating and ventilating apparatus, $4,000; new plumbing, $5,000; piping, wiring and fixtures for lighting, $5,000.

## PERSONAL

**H. R. Safford,** chief engineer of the Grand Trunk Railway, has been nominated for the vice-presidency of the American Engineering Railway Association.

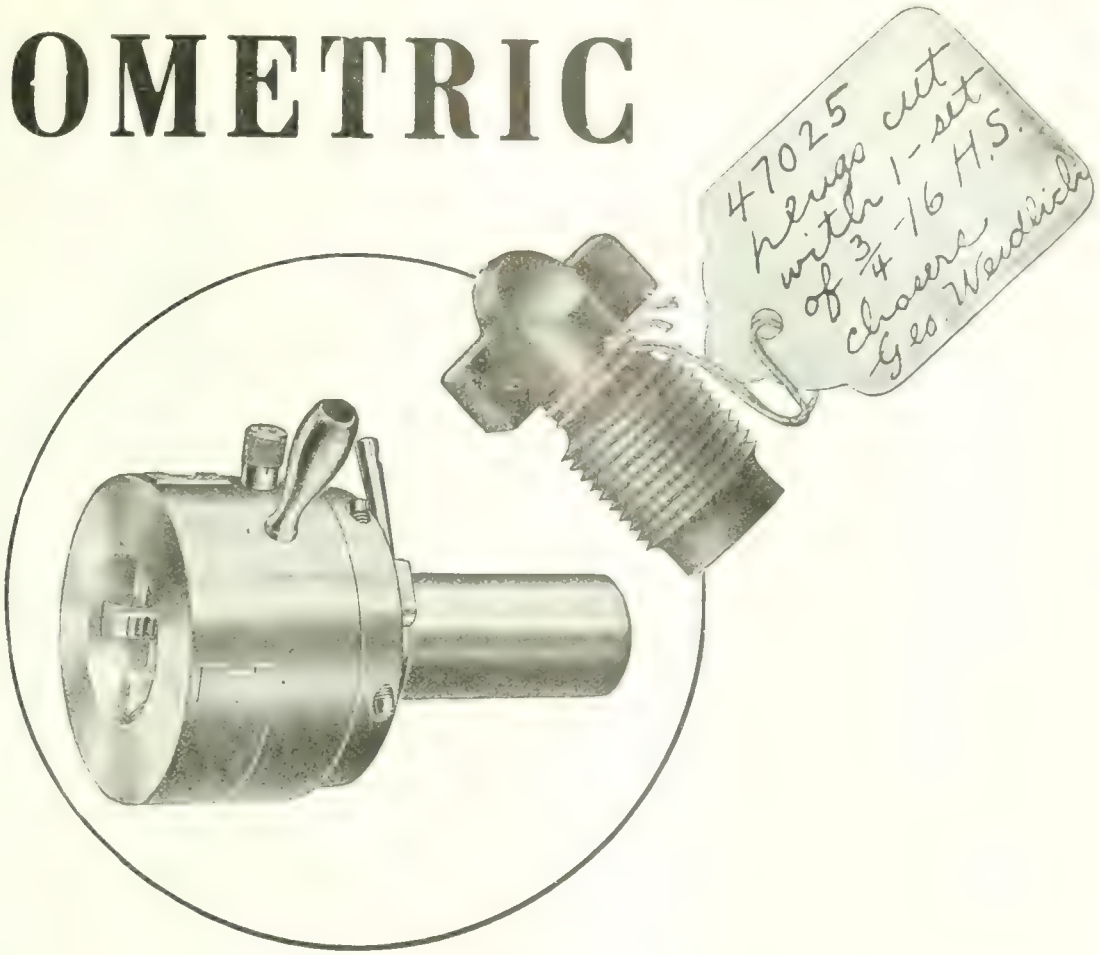
**Charles Spalding,** who was with the Gisholt Machine Co. for twelve years has been made general manager of the Amalgamated Machinery Corporation, Chicago, Ill.

**Fred W. Field,** editor of the *Monetary Times*, and a leading authority on financial and commercial matters in Canada, has been appointed British Trade Commissioner at Toronto with a territory that will probably embrace the entire Province of Ontario.

**Captain R. J. Durley, M.E.,** Montreal, has been made a member of the Order of the British Empire. Captain Durley, who is by profession a consulting engineer, specializing in heating and ventilation, holds a position in Ottawa under the Imperial Munitions Board.

**G. T. Milne,** British Trade Commissioner for Australia has been appointed senior British Trade Commissioner in Canada, in succession to Hamilton Wickes, who is for the present remaining

# GEOMETRIC



## One Set of Chasers in a Geometric Die Head has cut 47,025 of these Plugs

The man who has operated the Geometric Die Head says: "In all my twenty-five years' experience I have never known a die to cut as many threads as this set has cut on cast iron."

A quarter of a century of specializing in one line has brought Geometric Thread Cutting Tools up to the high water mark.

Arrange to do your threading with a Geometric. Let our catalogue tell you about it.

## THE GEOMETRIC TOOL COMPANY

NEW HAVEN, CONN., U.S.A.

*Canadian Agents:*

Williams & Wilson, Ltd., Montreal; The A.R.Williams Machinery Co.,Ltd., Toronto, Winnipeg and St.John,N.B.

bureau, in which capacity he will fol- duction of all articles purchased. This is a further step in the reorganization of the ordnance bureau.

**D. L. Derrone**, formerly identified with the Canada Cement Co., Montreal, engaged in the manufacture of munitions, for the Amalgamated Machinery Corporation, Chicago, is now works manager of Winslow Brothers Co., Chicago, specialists in architectural iron and bronze work for buildings, but engaged in making 6-in. shells.

**Peter Hay**, a prominent citizen of Galt, Ont., and well known as a machine knife manufacturer, died at his home in Galt on Jan. 14. He was born at Lauder, Scotland, in 1835 and came to Canada in 1857. Coming to Galt, he was identified with local steel industries before entering into business for himself in 1885. After conducting the business successfully for 30 years, the Peter Hay Knife Co. was organized and he retired from active management.

**Professor A. N. Talbot**, of the University of Illinois, has been elected president of the American Society of Civil Engineers. Professor Talbot is a graduate of the University of Illinois, class of 1881, and has been a member of the faculty of that institution since 1884. Since 1890 he has ben head of the Department of Municipal and Sanitary Engineering and in charge of theoretical and applied mechanics and has directed important investigational work in engineering materials, reinforced concrete, rail road track, hydraulics, water works, etc.

# TRADE GOSSIP

**The Dominion Steel Products Co.** of Brantford, Ont., has increased its capital stock from $500,000 to $1,000,000.

**The Canadian Cartridge Co.**, Hamilton, Ont., has been awarded a contract for the manufacture of brass cartridge cases for the United States which will keep the plant in operation for several months.

**The National Motor Show of Eastern Canada** is being held this week in Montreal under the auspices of the Montreal Automobile Trade Association on the third floor of the Almy Building.

**Bringing Coal from England.**—It is reported from Washington that the scarcity of coal in the United States has be- Atlantic ports.

During the past year there were only 161 suffered decrease by the lifting of rails to the extent of some 400 miles and sending the rails to France.

**The Herbert Morris Crane & Hoist Co., Ltd.**, Niagara Falls, Ont., announces that its plant at Niagara Falls is completed and is ready to turn out chain blocks, trolleys, travelling chain blocks, jib cranes and overhead travelling cranes.

**Chatham Building Permits.**—Building permits for the city of Chatham, Ont., for 1917 reached a total of $390,997. The total for the preceding year was $1,338,924, this amount including a permit of one million dollars for the erection of the Chatham plant of the Dominion Sugar Co.

**The Hydraulic Press Mfg. Co.** of Mount Gilead, Ohio, announce that their extensive new buildings are now occupied and the plant is again in operation to its full capacity. New and up-to-date equipment has been installed for the building of hydraulic presses, pumps and valves.

**Building Permits at Kitchener.** The building permits issued in Kitchener for the year totalled 207, and were estimated at $205,352. Forty-six new residences were erected valued at $117,925; eight business buildings, $47,900; 46 alterations or additions, $19,005, and 107 garages and smaller buildings, $20,522.

**Welland Building Permits.**—City Engineer D. Black reports that the building permits for 1917 reached a total of $211,334 as compared with $202,587 for 1916 which shows a satisfactory increase. The permits for last December however show a decline being only $1,000 whereas for the corresponding month of 1916 the value was $11,225.

**Sydney, N.S.**—That the building trade was good last year is evidenced by the fact that building permits in 1917 amount to about $415,00, while those issued in 1916 showed a total of slightly over $120,000. Included in last year's buildings is a fine eight-room brick school building on Argyle street, costing $56,000.

**Building Improved in City of Toronto.**—Normal building in the city of Toronto shows a substantial increase for the year 1917 as compared with the year 1916. In 1917 permits were issued totalling about seven and a quarter million dollars. Last year permits totalled $9,881,671, but these figures included the three-million-dollar permit for the Union Station.

**Montreal Board of Trade Officers.**—W. A. Black was elected president of the Montreal Board of Trade by acclamation last Friday. No opposition was made to any of the official positions, so that the rest of the "slate" were elected by acclamation, including John Baillie, 1st vice-president; George Sumner, 2nd vice-president, and W. A. Coates, treasurer.

**Lloyds Cut Insurance Rate.**—Lloyds underwriters last Saturday accepted war insurance on transatlantic cargoes at rates much below the flat rate of the Government, according to the "Times." This action probably is connected with the proposal to extend the Government's scheme, which in effect, would make such insurance on cargoes in British ships a Government monopoly.

**Lower Prices for British Steel Scrap.**—A new order reduces the maximum prices of British steel scrap, fixed by the Ministry of Munitions. On all classes, mixed or not with wrought iron or other material, except steel planings, turnings and borings, the price is changed from £5 5s. to £4 15s. per ton. Wrought iron scrap, mixed with steel or other material, is reduced from £5 5s. to £4 15s. per ton.

**Coal Tar Controlled in England.**—A cablegram from London says: "The Minister of Munitions orders that from Jan. 10 it is forbidden to take, accept or attempt to obtain delivery of any crude solvent naphtha or heavy naphtha except under license. From Jan. 15 no person shall burn or consume tar for firing, steam-raising or heating purposes. Dealings in coal tar subject to control of the Minister of Munitions."

**London Building Permits.**—A. M. Piper, building inspector for the city of London, Ont., reports that 843 building permits were issued during 1917 up to Dec. 31 having a total value of $837,890 compared with $926,125 for 1916 for 1,034 permits. There were 26 permits issued last December valued at $34,590, while for the corresponding month in 1916 31 permits were issued valued at $18,705.

**Record Mercury Output in U. S.**—Heavy increase in quicksilver production in the United States, largely used in war munitions manufacture, was announced recently by the U.S. Geological Survey, which placed the 1917 domestic output for the United States at 36,351 flasks of 75 pounds each. Its value is estimated at about $3,857,000. Not since 1883 had so much been mined. Production was 6,419 flasks larger than in 1916.

**Hydro Development in Eastern Ontario.**—The Ontario Hydro Commission propose to serve the towns of Picton, Wellington and Bloomfield, in Prince Edward County, by means of a 44,000 volt line from Trenton. A sub-station will be erected at Wellington, for serving Wellington and Bloomfield, and a 4,000 volt line will be built from Wellington to Bloomfield. A sub-station will also be erected at Picton to serve this town.

**Steel Freighter Launched at Vancouver.**—The steel freight steamer Alaska, built at the Coughlan yards, Vancouver, B.C., was launched successfully on Saturday morning in the presence of a large crowd. The bottle of wine was broken over the vessel's bow by Mrs. Koldrup, wife of the Norwegian Consul at Seattle. The Alaska has been under construction since last March. Her length is 427 feet and her gross tonnage 5,730.

**German Steel Output.**—The annual report of the German Steel League, the central organization of the industry, makes the significant admission that although the entire industry during the

# This, then, is the Very Essence of the BEAVER

## Easy-Working Principle:

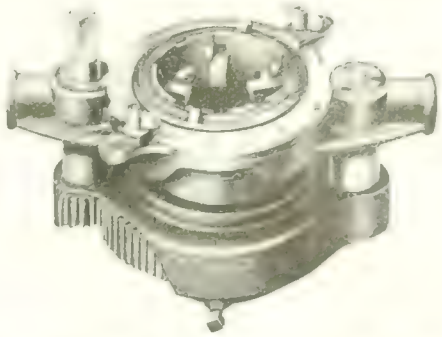
The dies are practically without taper and yet they cut an absolutely perfect tapered thread, because they automatically move away from the pipe during the threading operation, the dies removing less metal each turn, and consequently each turn of the die stock becomes easier, right up to the finish of the thread.

A man of ordinary strength threads 2-inch pipe with one hand in the time required to change dies in ordinary die stocks.

With Beaver Die Stocks, dies are set to thread all sizes of pipe by a simple turn of the handle.

Beaver Die Stocks are saving time and labor for far more than a quarter of a million users.

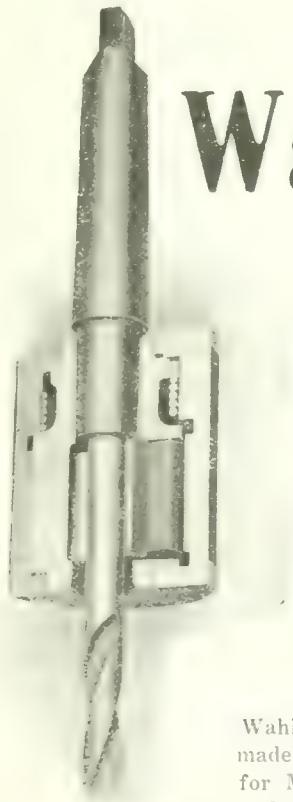
*For Catalog Write*



***Beaver Die Stocks are instantly adjustable to cut over or under, as well as exact standard threads***

## AIKENHEAD HARDWARE LIMITED

**17, 19, 21 TEMPERANCE STREET, TORONTO**



## Speed up with

# Wahlstrom Chucks

They will enable your men to make tool changes in less than two seconds—not stopping spindle.

They will perfectly centre the tool automatically—saving minutes every time a tool is changed.

They will grip the tool so it cannot slip—even at the highest speed of your presses—and never mark the shank.

They will make it possible to do your drilling, reaming, tapping and counterboring at top-notch speed.

They will profitably increase your output and better it.

**Write for Catalog**

Wahlstrom Automatic Chucks are made for straight shank tools and for Morse taper shank tools Nos. 1, 2 and 3. Recommended to you by "Canada's Leading Tool House."

*Aikenhead's*

**17, 19, 21 Temperance Street**
**TORONTO, CAN.**

Customs Receipts Drop in December. [illegible] for the Dominion for the month of December show a decrease of [illegible] as compared with the same month a year ago. The total receipts for December 1917 were $5[illegible], as against $11884,[illegible] in 1916. The total receipts for the nine months of the fiscal year, ending December 31, however, show an increase of $19,650,882 over the same period in 1916. In 1916 they totalled $106,[illegible], while the total to date in 1917 was $126,263,[illegible].

The Canadian National Clay Products Association will hold their sixteenth annual convention at the Prince George Hotel, Toronto, on Tuesday, Wednesday and Thursday, Jan. 29, 30 and 31. A number of interesting papers will be read by prominent manufacturers and others. The annual banquet will be held at the Prince George Hotel, Wednesday night, January 30, with Joseph Russell, M.P.P. as toastmaster. Further particulars may be obtained from the secretary G. C. Keith, 435 Grace St., Toronto.

**McGill Professor Now Cabinet Minister.**—Sir Auckland C. Geddes, K.C.B. who has been Minister of National Service since last summer in the British Government, was for three years Professor of Anatomy at McGill University, Montreal. Professor Geddes came to Montreal from Dublin in 1913 but returned to England in 1915 and later received a commission in the Northumberland Fusiliers. He was later appointed to the General Staff and raised to the rank of Grigadier General.

**Canada Buying Rails in U.S.**—The railroads in the United States are more actively in the market for standard section rails. It is confirmed that the Steel Corporation has taken some business at $55 to $57 per ton, and one lot of 2,500 tons is reported to have been sold to Canada at a considerably higher price. Small lots of standard section rails for early shipment have sold between $73 and $78 per ton. For late shipment the Steel Corporation prices are now $55 for Bessemer and $57 for open hearth rails.

Officers Chosen by Civil Engineers.—The election of officers of the Toronto branch of the Canadian Society of Civil Engineers, held at their annual meeting at the Engineers' Club last week, resulted in the following selections: Chairman, Prof. Peter Gillespie; secretary-treasurer, George Hogarth; executive committee: J. R. W. Ambrose, Willis Chipman, E. L. Cousins, Prof. Haultain, E. G. Heuson and R. O. Wynne-Roberts Reports of committees were read and other general business [illegible].

Newfoundland Paper for U.S.—A new [illegible] from Newfoundland, the shipping of pulp and paper to the United States, is disclosed in the customs returns. About 30,000 tons, mainly for distribution in small towns in the eastern state, were shipped during the latter half of 1917. Shortage of trans-Atlantic shipping forced Lord Northcliffe to seek a market in the States for the product which formerly had been shipped from his mills to England.

**B. C. Schooners on Australian Trade.** Of the Canada West Coast Navigation Co.'s fleet the following have done a voyage from British Columbia: Mabel Brown to Sydney; Margaret Haney, to Bombay; Geraldine Wolvin, to Sydney; Laura Whalen, to Adelaide; Jessie Norcross, to Adelaide; and the Malahat to Sydney. On passage are the Janet Carruthers, which sailed on August 21 for Adelaide; the Esquimalt, sailing the same day for Melbourne, and the Marie Barnard, which left November 13 for Sydney.

**Brompton Pulp Co. Acquires Two Concerns.**—The Brompton Pulp and Paper Co. has acquired two American concerns, the Claremont Paper Co., of Claremont, New Hampshire, and Wyman, Flint & Sons Co., of Bellows Falls, Vermont, so it was announced in Montreal recently at the annual meeting of the shareholders of the Brompton Pulp & Paper Co. It was stated that the two concerns in question had been acquired on a very reasonable basis, and no new financing by the Bromptin Co. would be necessary to complete the transactions.

**British Government Extend Trade Commissioner Service.**—The appointment of F. W. Field as British Trade Commissioner for Ontario is part of a scheme of the British Government to extend and develop the trade commissioner service in the Empire. It is now proposed to increase the number of trade commissioners in several of the dominions and to appoint commissioners in India and some of the Crown colonies and protectorates. Canada has hitherto been served by only one commissioner, who has headquarters at Montreal. G. T. Milne has been appointed to the Montreal office.

**Toronto Customs Record Revenue.**—Customs returns at the port of Toronto for 1917 made a new high record. The total was $35,677,000, an increase of $3,897,800 over the returns for 1916. That such a substantial increase was recorded is all the more gratifying by reason of the fact that the 1916 returns were an increase of some thirteen million dollars over those of 1915. Compared with pre-war customs revenue, the returns now pouring in represent an increase of 100 per cent. The largest monthly return in 1917 was in May, when it amounted to $3,546,256. The gain in customs revenue is due to a combination of circumstances. Actual importations have increased to a considerable extent and the total has been added to by the general increase in the cost of goods of all kinds.

**The Quebec Bridge Contraction.**—During the extremely cold weather between Dec. 18 and 30, when the temperature fell from 15 degrees above to 20 below zero, the Quebec Bridge contracted four and a half inches. Lt.-Col. C. N. Monsarrat, chairman of the Quebec Bridge Commission, issued this information to correct an announcement published in a daily paper that the recent very cold snap had effected a contraction of nine feet in the structure. Col. Monsarrat said the contraction of four and a half inches with a drop of temperature of 35 degrees was in accordance with expectations, and further, that provision had been made in the structure for expansion and contraction of 36 inches, which is sufficient to take care of a range of temperature of 180 degrees.

**Gas Waste in Western Ontario.**—Enormous wastage of gas due to defective distribution, leaky mains, improper service pipes and inadequate burners in factories were the principal disclosures made on Thursday at the gas investigation before the Ontario Railway and Municipal Board at Chatham, Ont. The board received suggestions as to the most feasible way in which the wastage could be overcome, including a recommendation that a thorough inspection of the entire system of producers, distributors and wholesale and domestic consumers be made by experts. That the wastage in some instances attained the proportions of from 25 to 50 per cent. of the supply was the statement made to the board by Superintendent F. W. James, of the Union Natural Gas Co. He attributed the wastage largely to leakage and the poor facilities provided by manufacturers and other large users for burning the commodity.

## MARINE

**Vancouver, B.C.**—The first of the wooden steamers building at the Western Canada Shipyards will be launched some time this week.

**Esquimalt, B.C.**—The Princess Victoria is still on the slip-way at Yarrows, Ltd., getting a shaft renewed and undergoing a general overhaul. She will soon be ready to resume the triangular run.

**Quebec, Que.**—The Canada Steamship Lines are establishing a plant at Cap de la Madeleine, near Three Rivers, for the repair of ships. It is intended that this shall replace the one destroyed some time ago at Sorel, but it will be larger and better equipped. The municipality is being asked for exemption from taxation. Some of the Steamships' fleet is wintering there.

**Vancouver, B.C.**—First of the fleet of twelve wooden schooners built in British Columbia to return to this Province, the Jessie Norcross reached here on Jan. 10, with a cargo of sugar for the British Columbia Sugar Refinery at Vancouver. She made a quick passage from Fiji, encountering favorable winds most of the way across. The Jessie Norcross was launched at North Vancouver by the Wallace Shipyards on April 29, 1917, and loaded lumber at Genoa Bay for Port Adelaide, Australia. She is to load an-

other lumber cargo in British Columbia for the Antipodes.

## TENDERS

**Ottawa, Ont.**—Tenders will be received until Feb. 5, 1918, for the elevators and hoist equipment required in the re-construction of the Parliament Buildings. All tenders to be based on the execution, erection and completion, together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for elevators and hoist equipment. The work of this contract shall be proceeded with immediately upon the signing of the same and continued as directed, in such a manner as to insure the completion thereof by Dec. 31, 1918. Plans and specifications, and any other information required can be obtained at the office of the General Contractor, P. Lyall & Sons Construction Co., Ottawa.

**Ottawa, Ont.**—Tenders will be received until Feb. 5, 1918, for rolled steel casements and bronze covered frames and sash for the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for (a) rolled steel casements (b) bronze covered frames and sash. Separate tenders to be sumitted for "a" and "b." The work included under this contract shall be commenced immediately on the signing of the same, or at such time as may be directed, and be carried out in such a manner as to insure the completion therequired can be obtained at the office of the of by Sept. 30, 1918. Plans and specifications, and any other information regeneral contractor, P. Lyall & Sons Construction Co., Ottawa.

## CONTRACTS

**Toronto, Ont.**—The Ontario Power Co. has awarded further contracts in connection with the extensions to the plant at Niagara Falls. The Canadian General Electric Co. was given the contract for the two generators to be installed, while the turbines will be purchased from the Tallahassee Power Co. The pipe-line contract has already been awarded to the Pacific Coast Wood Stave Pipe Co. The Hydro Electric Commission controls the Ontario Power Co., and is financing the undertaking.

## RAILWAYS

**Calgary, Alta.**—A survey for a new railroad line from Medicine Hat, Alberta, south through Coutts to connect with the main line of the Great Northern at Great Falls, Mont., and open a new outlet for the great stores of Canadian wheat in the prairie provinces, is reported in progress. The survey is in charge of C. B. Miles, of Calgary, for the Alberta-Hudson Bay Railway, it is said, but such a line has long been considered by the Grand Trunk Pacific Railway and also by the Canadian Northern as a feeder for the Hudson Bay Railroad when it shall be completed.

**METAL STAMPINGS**

We are manufacturers of stamped parts for other manufacturers.

We do any kind of sheet metal stamping that you require. Our improved presses and plating plant enable us to produce the finest quality of work in a surprisingly short time.

We can finish steel stamping in Nickel, Brass or Copper.

Send us a sample order.

**Brantford, Ont.**—Freight service on the municipal railway line between here and Paris has been discontinued and the passenger service curtailed by half with the object of conserving Hydro power. Further curtailment of the street railway service within the city is also expected.

## INCORPORATIONS

**McKinnon-Columbus Chain, Ltd.**, has been incorporated at Ottawa by L. E. McKinnon, D. S. Brisbin and W. A. McKinnon, all of St. Catharines, Ont., to manufacture chain and metal products of all kinds at St. Catharines, Ont., with a capital of $1,000,000.

**The Beaver Truck & Tractors Co.** has been incorporated to manufacture motor trucks, farm tractors, fire apparatus and vehicles at Walkerville, Ont., with $500,000 capital stock. Edward P. Brownell, Toronto; Charles J. Stodgell and Henry P. Crocker, Walkerville, are interested.

**Canadian Die Casting Co.** has been incorporated at Ottawa with a capital of $300,000 to manufacture iron and steel products of all kinds. The chief place of business is Montreal and the incorporators are: Harry A. Bertram, F. H. Markey, and W. W. Skinner, all of Montreal.

## CATALOGUES

**New Publication on Plastic Fire Brick.**—Under the title, "How Anyone Can Make a Jointless Gas-tight Furnace Lining," the Betson Plastic Fire Brick Co., of Rome, N.Y., has published a 16-page illustrated folder showing how the plastic fire brick made by them is used in forming one-piece linings for steam boiler furnaces. The old lining of fire bricks or blocks is first removed and the plastic material is then placed in the form of chunks, consolidated with a mallet and smoothed with a trowel, occupying the same thickness as the old lining. The special mechanical process used in the preparation of this material is said to eliminate expansion and contraction with temperature changes, so that not only sidewalls, but also door arches, rear arches and arches for Dutch ovens and other forms of furnace can be formed as solid, monolithic structures. After the aterial has been dried and set by a slow fire for four or five hours, the furnace can be put into full service. No molds or special forms are used. The same material is used for forming baffles in water tube boilers.

### U. S. COAL EXPORTS TO CANADA

REDUCTION in exportation of coal from the United States suggested by Fuel Administrator Garfield will probably not affect the rank of the United States as a coal exporting country. A compilation by the National City Bank of New York shows that the United States, prior to the war, held third rank as a coal exporting nation, but, with Germany now cut off from the rest of the world, it has taken second place.

Great Britain, Germany and the United States have for many years supplied the bulk of the coal used in international trade. In 1913 the total amount of coal exported from coal producing countries was in round figures about 200,000,000 tons, of which approximately 40,000,000 tons was bunker coal, while a considerable portion of that classed as exported went to the world's coaling stations to be supplied to vessels. The value of the bunker coal used in normal times aggregates $250,000,000 out of a total of $700,000,000 worth passing out of the coal producing countries. In 1913, the year preceding the war, Great Britain exported coal of all kinds amounting to 93,000,000 tons; Germany, 40,000,000 tons; the United States, 29,000,000 tons; while Austria-Hungary was fourth with about 9,000,000 tons.

Much of the 200,000,000 tons exported before the war went to adjacent territories and a much smaller amount than is generally supposed went overseas. In 1917 the U. S. exported about 32,000,000 tons, of which more than 17,000,000 tons went to Canada, and about 8,000,000 passed into the bunkers of ocean vessels. Exports of coal to Canada for the past year were the largest in the history of this country, and the value is placed at $58,000,000, about one-fourth of the quantity being anthracite. The total value of all the coal exported and passed into bunkers for the year amounted to $113,000,000.

### GREAT HOPES IN PAPER TRADE

IN the rapid advancement of the pulp and paper industry in Canada since 1910, when total values of exports of pulp and newsprint have leaped from $7,000,000 to over $43,000,000 and may reach $60,000,000 in 1918, Canadian financiers and public leaders recognize one of the most promising avenues for overtaking part of the country's adverse trade balance, particularly in the United States.

Nearly $80,000,000 of new capital has been invested in the Canadian pulp and paper industry during the last seven years. The value of exported newsprint paper has advanced about one thousand per cent. While some fears have been expressed that the most serious check would come through exhaustion of the timber limits, the recognition of this possibility by the mills themselves has introduced greatly improved fire guarding, and assures the adoption of more conservative woods operations in future.

As not more than 10 per cent. of the total newsprint of mills in Canada is used by Canadian publishers, the main problem of all the mills is to find a profitable market for the remainder, almost 2,200 tons a day. Hitherto the United States has taken about every pound of pulp or paper that the industries could

produce, and with the exhaustion of Eastern States forest supplies, this pressure upon Canadian mills is bound to become more acute.

Canadian mills have made no attempt to sell Uncle Sam anything but newsprint, content to take the big share of the home market in the finer grades, such as book and writing papers. The latter trade has been turned toward Canadian mills more and more since British competition was made more difficult from shipping interference of recent years.

One of the great hopes of the Canadian pulp and paper trade is that the peace arrangements will include a preferential tariff scheme allowing them a privileged entry to the United Kingdom, Australia, South Africa and elsewhere. Australia makes very little paper of her own and imports heavily from almost every European country as well as Canada and the United States. Scandinavian factories, and those of Holland and Germany enjoyed a heavy share of Australian trade for many years past, while Canada received a trifling total.

South Africa offers a market chiefly in wrapping and bag papers, book papers and cheap bonds, which have hitherto been supplied from England cheaper than the Canadian mills could figure. In India only the most elementary grades of paper are used and have been brought from Germany, Australia, Belgium and England.

In the market of the United Kingdom Canada's paper manufactures as well as the raw materials of wood pulp have been heavily outclassed by Scandinavia. For example, in 1913 Sweden sold the United Kingdom $11,500,000 and Norway $6,000,000 worth of wood pulp against Canada's $900,000 worth. In paper for printing or writing Canada's sales to John Bull amounted to about $600,000, while the Scandinavian countries took total orders of over $6,000,000.

**Largest Locomotive in the World.**—The greatest steam locomotive in the world has been put into service by the Baldwin Locomotive Works, Philadelphia, Pa. It is so gigantic that its boilers had to be made flexible at three different joints so that the locomotive could turn around a curve. It is more than 100 feet long and weighs some 150 tons. Twenty-four driving wheels, each standing as high as an average sized man, afford its traction. The driving wheels are distributed along the length of the locomotive in sets of four pairs, the wheels of each set being coupled together and driven by two giant steam cylinders. Under full steam the locomotive can exert an 83-ton pull on cars behind it, which means that it can easily haul a freight train two miles long and 23,000 tons in weight over an ordinarily good roadbed at an average of fourteen miles an hour, and possibly more. Bad roads will retard it only slightly.

# Oxyacetylene Welding and Cutting: Methods and Apparatus

By Stuart Plumley

*The necessity for preheating castings is pointed out and methods of preheating are described. The design of welding and cutting torches also is considered and the operation of these devices is covered in considerable detail; likewise the necessity for using high-grade welding rods and other supplies is emphasized. Reference is also made to the large amount of welding work done on the machinery of damaged German vessels interned in the States.*

IN considering the subject of oxyacetylene welding at prior conventions of the American Foundrymen's Association, attention has been centered largely upon the various classes of work which have been accomplished with the process, and in generally describing the equipment and gases used.

The process has now been employed so many years that practically everyone has a fair idea of it, and generally understands the equipment and the things it will do.

There is, however, an unfortunate condition existing, especially in the New England states, which is brought about by a lack of practical knowledge of the process, and, in particular a lack of knowledge of the metallurgy of iron and steel as it affects a weld. Amng some of the foundries and machine shops in this district, the impression seems to have gained ground that the process produces only a hard, brittle union of the two parts to be welded, and that the weld cannot be machined; also that a weld in cast iron has no particular strength. Nothing could be further from the truth than this impression. It has been brought about by a lack of study of the process, by the use of very poor filling rods, and especially by the use of a great variety of apparatus, with which the market has been flooded which is improperly designed and constructed, and which is directly responsible for failures.

Under these conditions it seems opportune at this convention to consider the process, as applied to foundry work from a more scientific standpoint and with a better understanding of the various features of the apparatus and its use which bring about success in welding. These various factors cannot be given too much consideration. It is upon them that the success of the process in each individual foundry is dependent.

### Preheating of Iron Castings

Iron castings should be carefully prepared for welding, and placed in such a manner that preheating may be accomplished without unnecessary handling. This preparation consists in cutting away the edges to be welded to an angle of 45 degrees on each side, to permit the operator to start welding at the bottom of the broken section.

As it is necessary to bring the temperature of the casting up to the point of maximum expansion very slowly and evenly, and as it is desirable to maintain this heat as nearly constant as possible during welding, it is usually best to place the casting in a rough brick enclosure so the heat may be properly confined.

Preheating should be accomplished either with a large oil or gas flame of moderate temperature, or with charcoal. A fuel oil, or kerosene oil burner, is perhaps the most convenient means for preheating. Two such burners operating through openings in the brick wall above mentioned will usually heat a casting evenly, without overheating any particular part.

During welding, these preheating burners may be shut off, if the heat is found to be too great for the operator, and, when the weld has been finished, they may be relighted and the casting again brought up to an even heat. It should then be completely covered with asbestos, heated slacked lime, hot ashes, or sand, and allowed to cool very slowly.

*Paper presented before the American Foundrymen's Association at Boston, Sept., 1917.

**Of the Davis-Bournonville Co., Boston, Mass.

the casting hard and brittle.

ing may be accomplished with an inexpart of or the whole casting. In this cause almost any fuel, like kerosene, fuel and does the work better than oxygen and acetylene. In some instances where the castings are large it would be im- the casting prior to welding so as to strained on cooling. Such preheating is always necessary where the casting is complicated or where there are several pansion and contraction would be re- panded, either in part or whole, before welding contraction, after the weld has been accomplished, will set up strains in some of the members, eventually, if not immediately, causing a break.

Care must always be taken, however, in preheating a casting to see that it is not heated so hot it will be warped out of shape. This is especially the case where there are machined surfaces, which must be kept true. Preheating slowly so that sudden temperature duced. Slow heating is essential espeof thin and heavy parts. Cooling in all instances, as stated above, should be accomplished as slowly as possible.

In the first instance, where the casting merely to save gas, the temperature to which this preheating may be carried makes very little difference, because this temperature will not ultimately affect the utility of the casting. If desired, it may be heated to a dull red heat. In the second instance, where the casting is complicated, or where there are machined surfaces, which must not be warped out of shape, the temperature of preheating must not be anything like as high as a dull red, but, on the other hand, it must be sufficient to expand the metal pro- place, it will not create a strain or break.

Definite rules for preheating are practically out of the question because in

### Proper Mixture of the Gases in the

the two gases, oxygen and acetylene, in proper proportions, and that it thoroughly and intimately mixes these gases.

In every oxy-acetylene torch, the two gases are brought together in some manner, the object being to produce a luminous cone of flame at the tip of the torch. If there is just enough acetylene, thoroughly mixed with the right quantity of oxygen, to produce complete combustion there will be, in the first reaction of the flame, no unconsumed oxygen or acetylene coming in contact with the weld, and the flame will produce very satisfactory results. But if there is an excess of oxygen, which cannot be consumed in the first reaction of the flame, this excess of oxygen of necessity plays upon the heated metal during the welding operation; and hence oxidizes or burns the metal. If there is an excess of acetylene instead of oxygen, the effect will, perhaps, be less harmful, but the increased amount of carbon which will be taken up by the metal tends to make the weld hard and brittle.

Before proceeding further with this discussion, it may be well to explain that in the oxy-acetylene torch we are consuming oxygen and essentially gaseous carbon. Acetylene contains approximately 93 per cent. carbon, the remainder being hydrogen, with exception of a few impurities, which need not be given consideration.

There are two definite stages of combustion in the oxy-acetylene flame; one is termed the luminous cone of flame. In this stage of combustion theoretically one part of oxygen and one part of acetylene burn, and yield hydrogen and carbonmonoxide. In the secondary reaction, which is usually called the enveloping flame, or the envelope, hydrogen and carbonmonoxide burn, taking the necessary oxygen from the air and produce water vapor and carbon dioxide. This secondary reaction forms an envelope of burning non-oxidizing gases, which practically surrounds the heated metal during the welding operation and prevents its absorption of oxygen from the air.

It is this enveloping flame and the complete combustion of the oxygen and acetylene delivered by a properly designed welding torch that makes it possible to produce efficient welds.

### Gases Will not Mix

The opinion seems to have become more or less prevalent in New England, with which the writer is specially familiar, that it is only necessary to lead the two gases together and to control them with two regulating valves in order to produce the required neutral flame. But, a great deal of experience has shown that this is not a fact. The two gases will not mix together intimately when brought into contact and passed through a channel. There must be some other means for mixing them and some definite way to deliver the gases in proper proportion. This is accomplished in properly designed torches by leading the gases through very small ports of proper diameter, so that the velocity in each instance is high. These ports are arranged at right angles to deliver the jets of gas in fast flowing streams, which strike together and produce a vortex.

In this manner the two gases are thoroughly and intimately mixed before they pass through the tip to the first stage of combustion. They are also mixed in as nearly the proportion of one to one as is practicable under working conditions, this proportion being determined by the diameter of the ports leading the gases together and the pressures at which they are delivered. It is, of

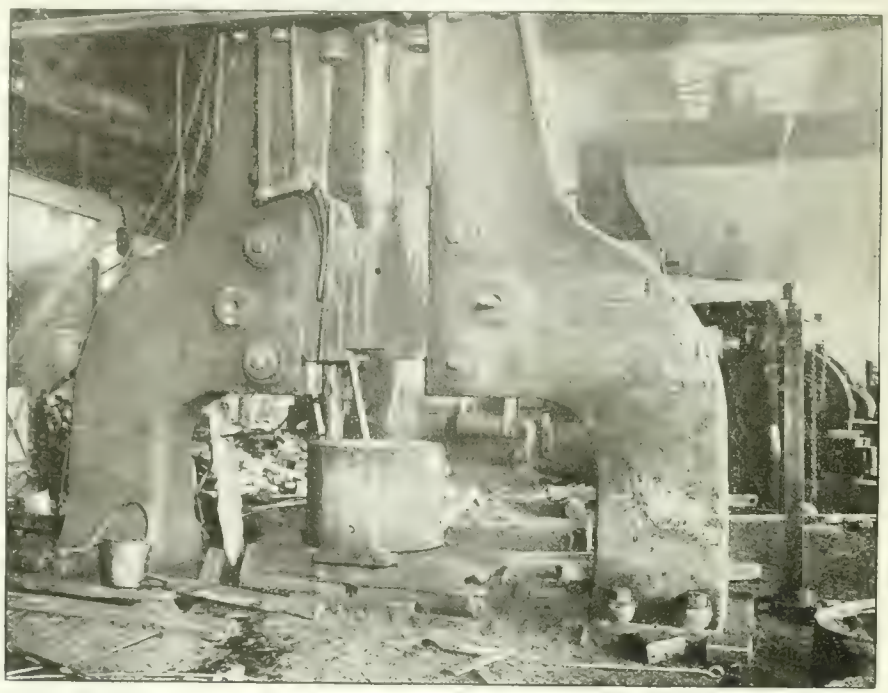

FIG. 3 LARGE STEAM HAMMER WITH WELDED LEG.

course, necessary that these pressures be each independent of the other, else the proportion would be out of control.

### Properly Constructed Torch

Fig. 1 illustrates a torch constructed upon these principles. The oxygen is led to the cast head of the torch through the upper tube under a pressure definitely controlled by the oxygen regulator. The acetylene is led to the cast head of the torch through the lower tube, the pressure being controlled by the acetylene regulator.

The interchangeable tips fit into the receptacle provided in the cast head of the torch by means of a ground joint, and each tip is arranged to produce a different size of flame for use upon different thicknesses of metal. In order that this may be accomplished, the size of the longitudinal bore through the tip and the diameters of the oxygen and acetylene ports must be in proper proportion so that at the pressures given by the regulators the right amount of each gas will pass through these ports. There is one oxygen port and two or more acetylene ports, the oxygen port being vertical and the acetylene ports horizontal. These ports meet at right angles at the upper end of the longitudinal bore through the tip. The streams of unlike gases, consequently, enter this longitudinal bore under high velocity and strike together, creating the vertex we have already described.

Fig. 1 clearly shows the luminous cone of flame produced and also the secondary reaction, or enveloping flame which surrounds the weld. The torch is held by the operator in such matter that the luminous cone of flame barely touches, or is a short distance away from the metal which is being welded. It will be very readily understood that if there is an excess of oxygen passing out of the luminous cone unconsumed, it will come in contact with the molten metal, which is being welded and cannot help but produce an oxidizing effect. This renders the weld much weaker than if complete combustion were attained.

It will, therefore, be appreciated that the design and construction of the torch is a very vital factor in the success of the process, and that a positively neutral flame must be secured. Many operators do not appreciate these facts and pay little or no attention to the character of the flame, and this results in failure which unfortunately cannot always be detected until the weld is placed under a strain.

A little thought on this subject will make it apparent that the two gases must be under a constant pressure to maintain the neutrality of the flame, and that this constant pressure is dependent upon the regulators attached to the sources of supply of oxygen and acetylene. It is, therefore, essential that both regulators be so designed and constructed that these pressures will be steady and even.

FIG. 1 A MORE DETAILED VIEW OF THE WELDED LEG

### Welding Supplies and Materials

In welding cast iron, aside from the importance of preheating and of thorough and proper mixture of the gases in the torch, there is another factor upon which the whole success of the weld is dependent. In making a cast-iron weld, whether the defect is a sandhole or a crack, the metal adjacent the break or hole must be chipped, or v'd, until the included angle between the faces of the break is 90 degrees. After the casting has been properly preheated and the torch applied, the sides of the break are melted away with the torch, and this entire opening slowly filled with cast iron fused into it by melting welding rods held by the operator. The operator ordinarily uses the cast iron rod as a puddling stick, with which he is able to work out slag, blowholes, etc.

The strength of the weld is dependent upon the composition of the welding rod used. It is a well-known fact that silicon in cast iron tends to promote the formation of graphite making the iron soft. Managanese and sulphur, on the other hand, have just the opposite effect. Cast-iron rods, therefore, should be high in silicon, and the grade of iron used in their manufacture must be of the very best. The rod must be cast in a heated metal mold in such manner that it is free from sand and is not chilled on the surface.

In New England, there are a great many cast-iron welding rods upon the market which contain very little silicon and are high in manganese and sulphur. They are also of a poor grade of iron of course are sold at a low price. The use of such welding rods tends to produce white or chilled iron, containing no graphitic carbon, making the weld intensely hard. The use of proper welding rods increases the amount of silicon in the weld, and decreases the manganese and sulphur, enabling the operator to produce a soft weld, which may be machined without trouble. It would, perhaps, surprise a good many people to know how many jobbing machine shops in Boston will turn down an iron casting if the machining upon it involves the machining of a welded part. Much of this trouble lies in the use of the cheaper grades of welding rods. Even some of the larger companies, who depend entirely upon purchasing agents to buy supplies, price being the only consideration, experience identically the same difficulty, because the welder is utterly unable to produce a satisfactory weld with a poor welding rod.

The manufacture of good welding rods cannot be carried out in an ordinary foundry, as the iron is not suitable for the purpose. The production of such rods is the work of a special foundry, properly equipped, and with accurate knowledge of the requirements.

A good scaling powder is, also, essential in making a cast iron weld. Melted cast iron has a great affinity for oxygen, which combines with it to form an oxide of iron, or slag. The oxide is lighter than the melted metal and does not melt at quite so low a temperature. As it rises to the surface, a great deal of it can be removed by scraping it away with the welding rod. The object of a flux in this connection is to provide a chemical which at the high temperature involved will break up the oxide into its component parts. Two chemicals in the flux combine with the oxygen in the slag, releasing the iron, and allow the oxygen to pass off in the form of carbon monoxide, or carbon dioxide.

When the torch is first applied to cast iron and the metal becomes fused, the molten metal from the two pieces to be welded will not run or melt together on account of the film of oxide covering

the metal clear and mirror like, and unmetal will quickly flow together in conjunction with the melted welding rod.

If, in the various foundries where cast-iron welding is being accomplished, the foreman or manager of the department would give more attention to the grade of cast iron rod he is using, his department would be far more successful in producing proper welds. It requires, as a rule, but a few cents worth of welding rods to complete a weld, and the value of an expensive casting may be dependent absolutely upon the strength of the material used. Therefore, a proper rod cannot be considered from a standpoint of price. The best grade of rod obtainable is by far the least expensive.

It is not the purpose in this paper to attempt to refer to or illustrate the many very important pieces of work which have been accomplished by the oxy-acetylene welding process. We are illustrating, however, a particularly interesting piece of work recently completed in Chicago.

Figs. 3, 4, 5 and 6 are reproductions of photographs of a steam hammer, the cast-iron leg of which was broken completely off. The break occurred on a Tuesday morning. On Tuesday afternoon preparation of the casting began. It was necessary to clip, or "v", the break clear around the leg. Welding was started on the following Friday and completed on Saturday night. The hammer was assembled Monday morning and put in operation the following Wednesday morning. It has been working day and night, since the break was repaired.

In all, the repair required 16 linear feet of welding in cast iron ranging from 2 to 3 inches in thickness; 2,000 cubic feet of oxygen and about 1,800 cubic feet of acetylene were consumed. The welding required the services of four men, each relieving the other.

Fig. 6 shows the leg lying flat on the floor of the shop, the break having been enclosed in a rough brick furnace. In this manner the heat was confined, and the temperature maintained to a very even degree. Preheating was accomplished with large fuel-oil burners. The job is interesting, because it will be readily appreciated that the tensile strength of the weld must, in this instance, have been sufficient to stand up under the very severe strain to which a machine of this type is subjected.

There are many, many other instances of similar work, but in the majority of them, where the castings are large and heavy, the principles of operation remain the same. Care and skill, good apparatus, and suitable welding supplies are required to make such work successful. The skill, however, is not beyond the in-

such skill can be attained without serious difficulty under proper conditions of instruction.

A very interesting application of the process on cast-iron was the welding of the broken cylinders of two of the interned German steamship which were recently taken over by United States gov-

liner, starboard second intermediate pressure cylinder.

Welding patch about 32 inches in starboard second intermediate pressure cylinder.

Welding patch about 32 inches in starboard high pressure cylinder.

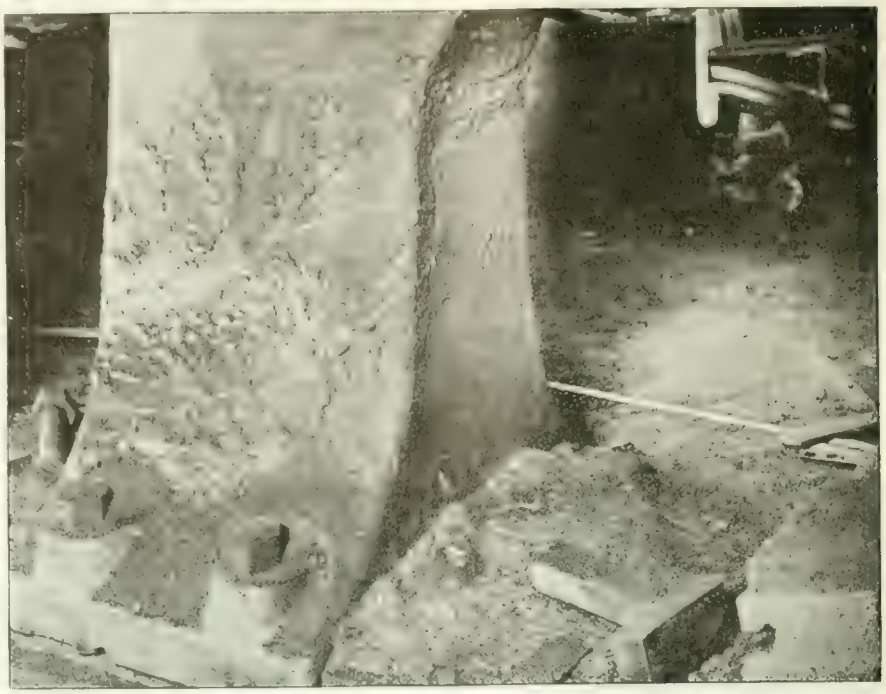

FIG. 5. CLOSE-UP VIEW IMMEDIATELY AFTER COMPLETION.

ernment, and repaired at a certain navy yard. These cylinders were badly broken. In many instances pieces had been entirely removed from them and disposed of. In such instances, it was necessary to recast new parts the shape of the broken ones and weld these new parts into place.

Perhaps, the only way the extent of the welding accomplished on these vessels may be appreciated, would be the consideration of the following list of breaks which were repaired:

**First Vessel.**

Welding crack about 19½ inches long in starboard low pressure cylinder liner.

Welding crack about 27½ inches long in port low pressure cylinder liner.

Welding four broken places each about 8 inches long on end of liners, two on port low pressure cylinder, one on port second intermediate pressure cylinder, and one on starboard second intermediate pressure cylinder.

Welding crack about 12 inches long in cylinder liner of starboard second intermediate pressure cylinder.

Welding about 33 inches on port high pressure cylinder.

Building up about 18 inches on patch on port first intermediate pressure cylinder.

Welding patch about 53 inches on port first intermediate pressure cylinder.

Welding patch about 46 inches on port second intermediate pressure cylinder.

Welding patch about 73 inches on starboard low pressure cylinder.

Welding patch about 73 inches on starboard second intermediate pressure cylinder.

Welding patch about 80 inches on port low pressure cylinder.

**Second Vessel.**

Welding two broken places on flange of elbow about 9 x 3 inches.

Welding flange about 57 x 4 inches on starboard intermediate pressure cylinder.

Welding slide valve of steam chest 9 x 4 inches on starboard intermediate pressure cylinder.

Welding crack about 12 inches in bushing of starboard second intermediate pressure cylinder.

Welding two pieces on end of flange about 13 x 5 inches on starboard second intermediate pressure cylinder.

Welding patch about 8 x 6 inches on cylinder

Welding flange about 39 inches on starboard high pressure cylinder.

Welding piece about 7 inches long in steam chest, valve of cylinder liner, starboard second intermediate pressure cylinder.

Welding patch about 54 inches on port second intermediate pressure cylinder.

Welding flange about 36 inches on port second intermediate pressure cylinder.

Welding flange about 48 inches on port high pressure cylinder.

This work was all accomplished between June 21 and July 23, approximately one month. It is difficult to believe that it could have been accomplished with any other process or by mechanical means.

Similar work was attempted with the electric arc, but did not prove as successful as with the oxy-acetylene torch. The use of the electric arc, as applied at other navy yards to similar work, necessitated a steel casting, the shape of the broken part, as the arc does not produce satisfactory results in connection with cast iron. The new cast-steel part was attached to the main body of the cast iron cylinder through the use of steel spuds screwed into the casting and set as close together as possible. It will be appreciated that such a joint would be partly a mechanical joint, and partly a welded joint, and could not be expected to be as efficient as a joint which was welded throughout.

As the oxy-acetylene torch is especially adapted to welding cast iron, the welding of these cylinders became largely a matter of proper preheating to take care of expansion and contraction. The weld possessed ample tensile strength, and the results were very satisfactory. All the cylinders were carefully tested under rigorous conditions and stood up under severe requirements.

It would be very interesting to show photographs of these broken and welded cylinders, which were taken at the time, but the necessary permission from the government has not been obtained. It is needless to say that repairs to the two German vessels in question have been made with much greater rapidity and at much less expense than if it had been necessary to replace the broken cylinders and parts with entirely new castings.

### Cutting in the Steel Foundry

The cutting process is now generally understood by the great majority of foundrymen. It is, of course, not applicable to the iron foundry, but is exceedingly useful in the cutting risers in the steel foundry.

Cast iron cannot be cut with the oxy-acetylene torch, but cast steel is quickly and easily cut at a very reasonable cost. It is so much more convenient to take the torch to the castings than to transport a heavy casting to the saws and strap it into position for sawing. Without doubt the cost of sawing a riser is less than the cost of cutting it with the oxy-acetylene torch, unless consideration is given to the time required to place the casting at the saw, and the much greater length of time required for sawing. When all factors are considered, including the output of the foundry, a cutting torch is found to be not only an economy but an actual necessity, and to-day there are very few steel foundries in the country where one or more cutting torches are not in continual operation.

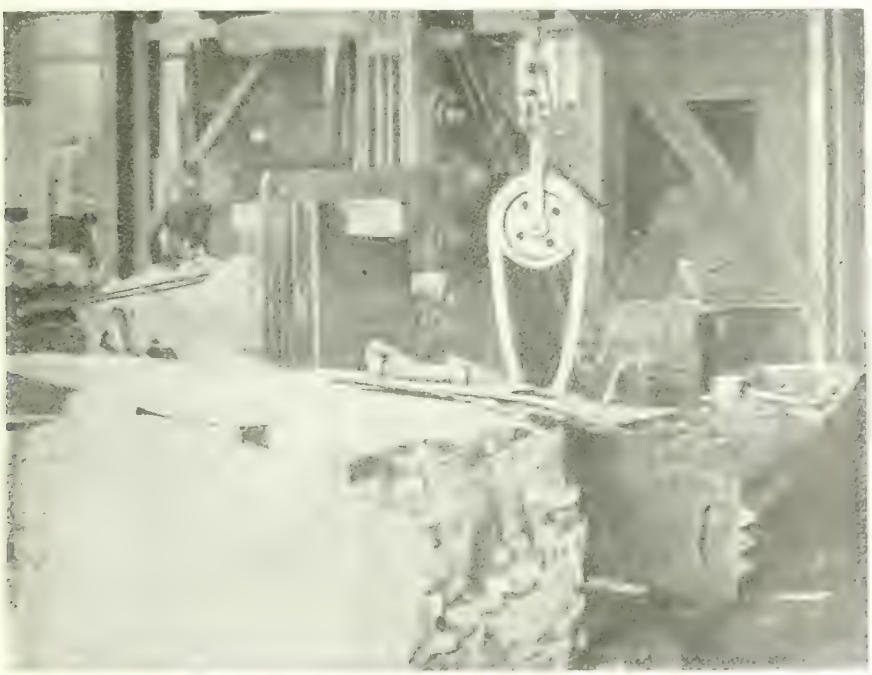

FIG. 6 PREHEATING LEG WITH ROUGH BRICK FURNACE TO RETAIN HEAT

In connection with cutting, as in welding, it is essential that the torch be properly designed and constructed in order to do the greatest amount of cutting with the lowest possible consumption of oxygen and acetylene. A properly constructed torch is illustrated in Fig. 2. As in the welding torches, the two gases are led together through very small ports, under high velocity, but as cutting is an oxidizing process, it is not necessary that the preheating flames be absolutely neutral in character, as is essential to good welding. It is, however, necessary that the gases be applied and the tip of the torch so arranged that the torch will cut cleanly and efficiently any thickness of riser to which it may be applied. This is accomplished with the torch shown in Fig. 2 through the use of interchangeable tips, which are furnished in many different styles, each style suitable for the class of work in view. For light and intermediate cutting, the greatest economy is obtained through the use of two preheating flames; for heavy cutting, where a good deal of sand is encountered, it is sometimes desirable to use four, or more, preheating flames.

In all probability, cutting apparatus gets harder usage in steel foundries than in other shops, partly due to the class of labor generally operating the torch and partly to the prevalence of sand in the riser, which causes the oxide to continually flare back. For this reason, to produce successful results and give efficient service, a cutting torch must be very substantially constructed. In general, cutting is far easier than welding and can be mastered by a man of very ordinary intelligence in a short time.

### Conclusion

The oxy-acetylene process in the past 12 years has made progress, which can scarcely be appreciated unless one is thoroughly familiar with each step as it has been developed. Perhaps, this progress is best expressed in terms of oxygen, as the consumption of oxygen is indicative of the use of both welding and cutting apparatus. It is safe to say that 12 years ago there was practically no oxygen consumed in this country, either for welding or cutting. To-day a rough estimate of the volume of oxygen consumed in connection with the process is between 40,000,000 and 50,000,000 cubic feet each month.

This development has been so rapid, however, that sufficient consideration could not be given to the proper instruction of skilled operators. In the past most men who have learned to weld or cut have done so despite the difficulties which they encountered and under conditions which did not produce the most successful results. It is without doubt appreciated that to-day there is more urgent necessity for skilled operators than for development along other lines. This need is being met by the establishment of welding schools where complete courses of instruction are given. The foundryman of to-day can profit most in connection with the process if he will give careful attention to the kind of instruction given his operators. Even in the case of a skilled welder, a few weeks in a welding school will bring out methods of operation with which he is not familiar, and will teach a great deal which will be new and useful. His efficiency and the efficiency of the process is largely dependent upon his own knowledge and skill in connection with his trade.

## CANADA GETS COAL SUPPLY

THERE has been much comment and speculation regarding how Canada would be treated under the restrictions recently placed on coal shipments by Dr. Harry A. Garfield, American Fuel Administrator. It was first thought that Canada would receive an allotment for the first three months of this year equal to the actual shipments during the first three months of last year. Later it was learned that licenses had been issued to American shippers for the export to Canada of only 40 per cent. of last year's actual shipments and that the Canadian Fuel Controller. C. A. Magrath, held licenses for another 40 per cent. of the amount, but these latter had to be approved by Dr. Garfield before they were valid.

### Licenses for Coal

A letter enclosing licenses for specified quantities sent to American shippers by the American Fuel Administration clears up the situation. Licensees are requested to "note especially the following points:"

"(1) C. A. Magrath, Fuel Controller of Canada, Ottawa, by arrangement with the United States Fuel Administration, has been granted a considerable tonnage, and he has the privilege for the period mentioned to call on this Administration to issue permits to any shippers who apply to him.

"(2) All coal leaving a United States port of exit after midnight December 31st, 1917, will be reckoned as part of your alloted tonnage for the months of January, February and March, 1918.

"(3) Shippers are required to report

allotments as given in the enclosed permit limits the amount of coal you are at liberty to export to Canada during the

### CAR SHORTAGE AFFECTS COAL SITUATION

HON. J. D. REID, Minister of Railways [illegible] that Canada's transportation system was greatly hampered as a result of the holding by American railways of some 22,000 cars belonging to Canadian railways. The Minister said everything was being done to have these cars released for Canadian service. Although special efforts seem to have been made by Mr. McAdoo, Director-General of American Railways, under the control of the United States Government, to have the bulk of these cars returned, so far nothing had really been accomplished.

"We have no shortage of motive power," added the Minister. "There are thirty-two new powerful locomotives ready to put into service as soon as they are required, while the seven thousand cars ordered in May last are at present in process of being delivered."

Referring to the possibility of transporting coal from the Crow's Nest line for consumption in Ontario, the Minister stated that it would be practicable next year. At present it would be impossible owing to the scarcity of cars. The long haul would also take considerable time. To bring coal from the West during the summer was possible, and, he would advise such a course. With coal coming from the West and the coal regions in the United States, Ontario would be amply provided for during the winter.

### GAS SUPPLY DEPLETED

THE investigation into the natural gas situation in Western Ontario before the Ontario Railway and Municipal Board at Chatham, Ont., last week, revealed the fact that the Tilbury-Raleigh gas field is being rapidly depleted, and that it will not be possible to supply all the demands being made on the producing companies for gas both for manufacturing and domestic purposes.

F. W. James, Superintendent of the Union Gas Co., in his evidence stated that with all manufacturing concerns cut off there will be a domestic supply good for some few years, but the supply is going down fast. He declared that for his company to cut off manufacturers and allow other producing companies working in the same field to send gas out for manufacturing would not materially lengthen the life of the field.

Gas from this field is sent as far east as Hamilton and Brantford by the Southern Pipe Line Co. and the Glenwood Oil & Gas Co., while the Union people send gas to Windsor, Chatham, Sarnia and a few smaller places in Essex and Kent counties. The Canadian Gas Co. also supplies gas for Wallaceburg and some for the Sarnia line.

It also develops that there are a number of contracts regarding the supply from the field and these will cause confusion. The Beaver Oil & Gas Co. had certain contracts, the Volcanic Oil & Gas Co. certain other contracts, the United Fuel & Supply Co. still others, and then the Union Oil & Gas Co. practically an amalgamation of all has still other contracts.

Contracts affect not only leases of land for production purposes, but also the delivery of gas to certain municipalities. It is contended that Sarnia, Windsor and Chatham each has original contracts with some one or other of the companies which give the right to all gas from certain sections.

The question which now arises is whether or not the original wells are exhausted and what the position of the Union Gas Co. is regarding these contracts, so far as wells are concerned which were drilled after the companies were all united.

### AMPLE SUPPLY OF STEEL FOR U.S. GOVERNMENT

STEEL manufacturers in the United States emphasize the fact that no delay has been occasioned to Government work of any kind for lack of steel, notwithstanding the compulsory cutting down of many mills in the last ten days. So diligent have the steel plants been in providing rolled products for all war contracts that most manufacturing plants have had surplus steel supplies to carry them over such barren spots in mill shipments as have occurred recently. Government needs will continue to be supplied first at all hazards, but as the worst is over, as far as furnace and mill operations are concerned, no uneasiness is felt concerning possible delay in war work at any point. Exception may possibly be made of the Chicago district, where curtailment of output has been most severe. Taken as a whole, however, Chicago industrial plants now are operating 30 per cent. of capacity. The Steel Corporation subsidiary plant operations in the Pittsburgh district are back to almost 50 per cent. of capacity.

Steel output, however, is again threatened by a famine in ferro-manganese which is likely to develop in sixty to ninety days if there is not a radical change in the situation. The most serious factor is the continual withdrawal of ships from the Brazilian trade and the United States to-day is largely dependent upon Brazilian ore from which to make manganese.

Stocks of manganese, which are not evenly distributed, are being steadily reduced and probably will be exhausted early in April if output does not gain over consumption in the next two months. Importations of British manganese are decreasing from month to month, and probably will be suspended altogether in a few months. The supply of manganese ore from Cuba and India does not compensate for the falling off in imports from South America. The steel works are using more spiegeleisen, which is a low grade manganese alloy, but the current supply is scarcely sufficient to eke out the decrease in manganese supplies.

Large steel companies that are producing manganese are better informed concerning the outlook for ferro-alloys than are small consumers and are making some effort quietly to provide for future needs. The smaller consumers seem strangely indifferent to the threatened shortage of manganese, if they have awakened to the seriousness of the situation. They are making no effort to cover future requirements and importers, in an effort to avoid creating excitement, are most conservative.

### REPORT OF BOILER INSPECTION IN ONTARIO

THE Boiler Inspection Department of the Trades and Labor Branch, Department of Public Works for the Province of Ontario, completed its year on Oct. 31. The annual report prepared by D. M. Medcalf, chief inspector of steam boilers, shows that a large amount of work has been done by the department during the past year.

**Work of Inspection by this Branch of the Department of Public Works, for the Fiscal Year Ending October 31, 1917.**

| | |
|---|---|
| New boilers inspected in the Province of Ontario | 235 |
| New boilers inspected in the United States | 53 |

Recently a man bought a second-hand automobile, which turned out to be a cripple on four wheels rather than a pleasure vehicle. He was describing some of the patient's symptoms to a friend.

"I take it, then, that she rattles a good deal when you run her?"

"Rattles!" said the owner of the car. "She sounds like a skeleton having a shaking fit on a tin roof!"

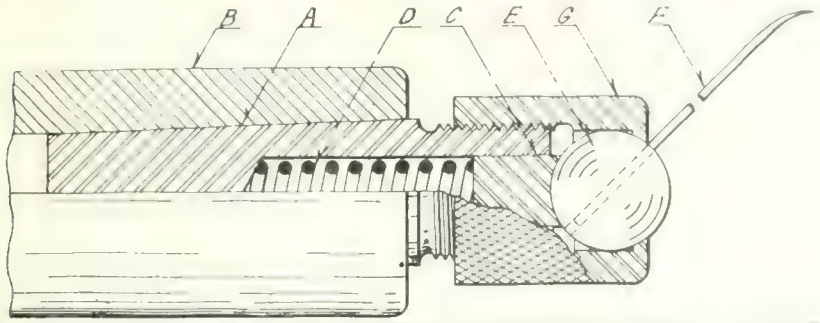
# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

## CENTERING DEVICE

By R. Hamilton

MUCH of the ordinary run of machine shop work, particularly that done upon centres in the lathe, can be placed in the lathe and machining started, the only preliminary details required being the drilling of the centres in the end of the piece. The same might be said of face plate or chuck work where the piece can be trued up by means of a piece of chalk or lead pencil. However, in the setting of work in the lathe or other machines, where greater accuracy is involved, such as jobs where the work is laid out on the bench for subsequent machining, it is necessary to align the work from lines previously determined, and any variation in the setting up means a corresponding error in the finished work.



DEVICE FOR USE IN TAILSTOCK SPINDLE FOR CENTERING FINISH CYLINDRICAL WORK.

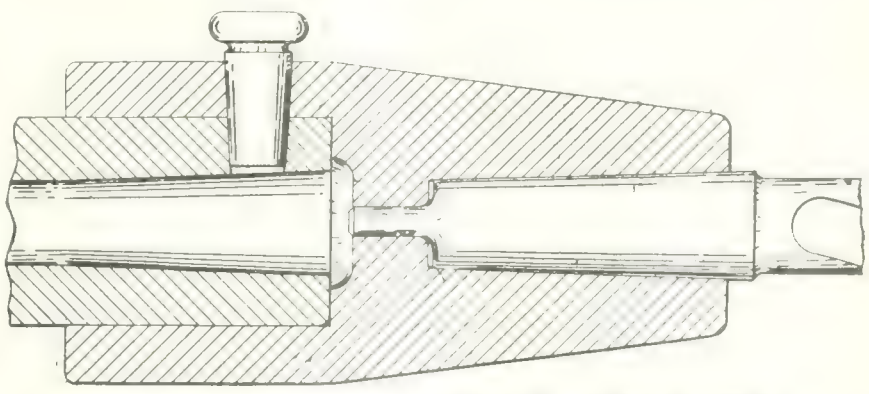
A simple device for setting up of finished cylindrical work, or pieces on which has been described an indicating circle, is illustrated herewith; it can be readily adjusted to any desired position by a slight pressure of the finger. The shank A of the attachment is fitted to the tail stock spindle of a lathe, or the spindle of a drilling machine. A hole bored in the front end carries a small plunger C and a compression coil spring D. The ball E, that carries the indicating wire F, is retained by the knurled nut G, and when this is screwed to position the reaction of the spring upon the plunger creates sufficient friction between the latter and the ball to retain the wire in any desired location and yet provides a convenient means of easy and instant adjustment.

## ACCURACY OF THE DEAD CENTRE

By J. H. R.

WHEN work is being performed in the lathe, that requires to have a central hole drilled, it is the general practice to secure the drill in the tail stock spindle, either directly in the centre chamber or by means of a special socket, the female part of which carries the shank of the drill while the male portion is inserted in the hole usually occupied by the dead centre. This latter method is the one generally adopted. Frequently, however, the pressure of the cut is so great that it overcomes the friction in the tapered socket and slippage results. This invariably takes place in the tail stock spindle and tends to destroy the accuracy of this essential part of the lathe. Should these conditions occur very often the hole becomes scored, and when work is being turned on the centres it may be found that accurate results are impossible. The centre may appear to fit very well but the unavoidable wear that takes place when a drill socket slips will eventually destroy the alignment and also the rigidity of the dead centre when it is placed in position.

To eliminate the trouble that has often arisen from this cause the holder here shown was constructed and used with very good results. By this method nothing is ever placed in the centre hole but the dead centre, and by keeping this free from dirt its accuracy is always maintained and the fit of the dead centre remains constant. The holder is made to fit snugly on the outer portion of the spindle while the tapered bore on the forward end is made to fit the shank of the drills being used. The holder is prevented from revolving by means of the tapered locking pin.



ADAPTER TYPE OF DRILL SOCKET FOR USE ON TAILSTOCK SPINDLE

## CUTTING COMPOUND ON CAST IRON

By H. Middleton.

THROUGHOUT all of our training and experience we have heard of cast iron as a metal to be worked dry, except for tapping. We all know what a drop of oil will do to a finishing cut on a cast iron surface—even the laying on of a semi-greasy finger will produce a spot that the flat finishing tool "skates" over.

But in threading grey iron castings cutting compounds of the milky kind have come into everyday use. Take the manufacture of pipe fittings, for instance, and the compounds have entirely upset accepted ideas. Taps and dies on that work are run at a high rate of speed and are kept flooded with the liquid. And the tools stand up longer at present rates than they did at the old speeds dry. The production meanwhile has been doubled.

On milling the use of compound has not been so successful. One firm that did a great deal of end and straddle milling on cast iron parts experimented with the compounds with a view of increasing speeds and decreasing cutter wear, but found that while the compound kept the cutters cool at high rates of speed, the accuracy of the work was sacrificed. The effect on the work was to glaze the cast iron surface and dull the cutters.

## GRIPPING AND LOCATING METHODS FOR MACHINING LINK

By F. H. Mayoh

IN manufacturing the connecting link shown in Fig. 1, which has a radial groove cut in it, some interesting tools are used, especially so for performing the second operation which consists of facing one side of the bosses, facing the groove pad and turning the groove. In performing this operation ten parts are handled simultaneously. The first operation consists of milling the two bosses on the side opposite to the groove while

the third or last operation consists of [illegible] the holes in the [illegible].

Referring to Fig. 1, which shows the connecting link and its principle dimensions, the first operation (machining the bosses opposite the groove pad) is accomplished on a vertical milling machine using a large surface mill. In holding the piece at this time advantage is taken of the draft angle on the forging.

The fixture used in holding this piece Fig. 2 is clamped to the milling machine table, the work is held between two vee blocks one of which A is securely held in [illegible] and dowels while the other vee block B is adjustable and is used for clamping purposes, this being operated by screw C. Gripping the work between these two vee blocks securely [illegible] the same as the blocks are beveled to conform to the upper draft angle of the work at X. In milling these bosses the cross-feed of the machine is used as by feeding the work in the direction of the arrow both faces are machined at the same time, the cutter being large [illegible] to cover both bosses.

The second operation shown in Fig. 3, is accomplished on a lathe, the work being [illegible] by the draft angles on the two bosses. Refering to the illustration A is a special face plate screwed on the spindle nose, B is a steel ring held by means of screws to the face plate. This ring has ten notches X cut into it to receive ten pieces of work.

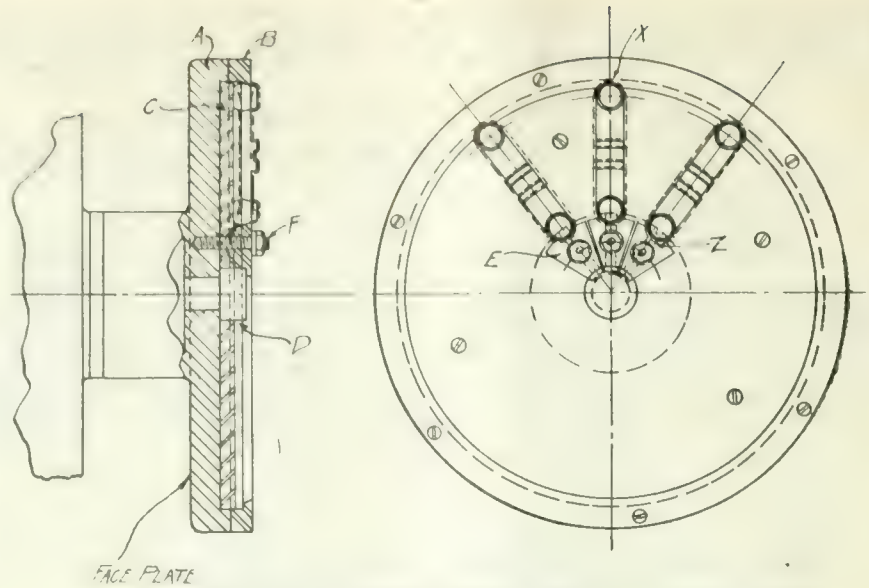


FIG. 3. FIXTURE FOR TURNING RADIAL SLOT AND FACING BOSSES.

The steel ring C is used as a seat against which the bosses that were finished in the first operation are clamped. This is also held to the face plate by screws. In the center of the face plate a plug D is driven while ten clamps E (one for each piece) with clamping screws and nut F complete the fixture. Each piece is securely clamped separately in the manner shown, while the tongue Z in the clamps prevents them from turning.

With this holding arrangement each piece is properly located so the axis through the bosses will pass through the center of the lathe spindle, and this also brings the pad for the radial seat in the correct location. The bosses and the radial seat being in the same plane, these are faced by tools in the rear cross-slide block while a tool in the front cross-slide block is used for turning out the radial groove. The tool used for machining the groove is of the narrow cutting-off type and is fed across the width of the groove, minus the width of the tool using block for gauging the depth of the groove and also for the width of same.

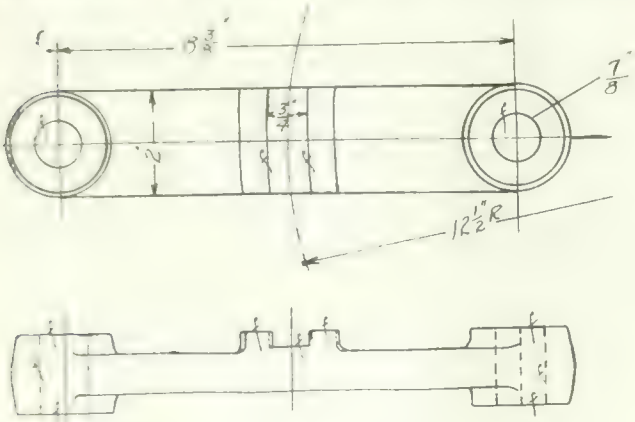

FIG. 1. DROP-FORGED LINK OF MACHINE STEEL WHICH IS TO BE FORGED

Having completed the milling and turning operations we next proceed to bore and ream the two holes in the bosses. This is done on a drill press, using the template Fig. 4 for guiding the drill and reamer. The fixture Fig. 2, which was used while milling the work is again used for holding the work. In this operation the work is held in much the same manner as shown in Fig. 2, except the grooved side Z is up, just the opposite to what it is shown. The template is placed on the work using the groove A Fig. 4, for locating purposes. Two pins B and C locate the template sideways. In drilling the holes these are first spotted by a drill that will fill the bushing which is reamer size. Following this a drill 1/64 small is run through the bosses and this is followed by reaming to standard size.

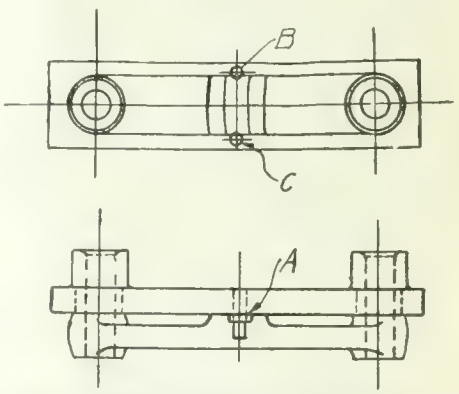

FIG. 4. TEMPLATE FOR DRILLING AND REAMING BOSSES.

Tooling up the link in this manner produces very good work and is a reasonably fast method of machining the same.

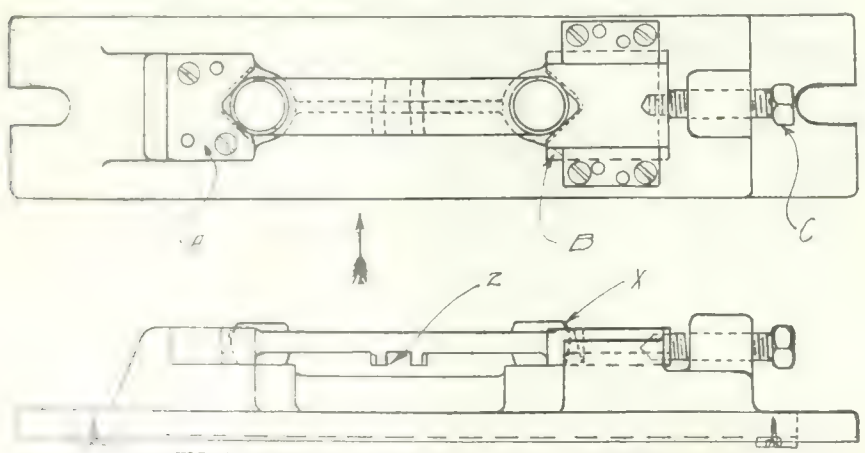

FIG. 2. METHOD OF MILLING FACE OF BOSSES.

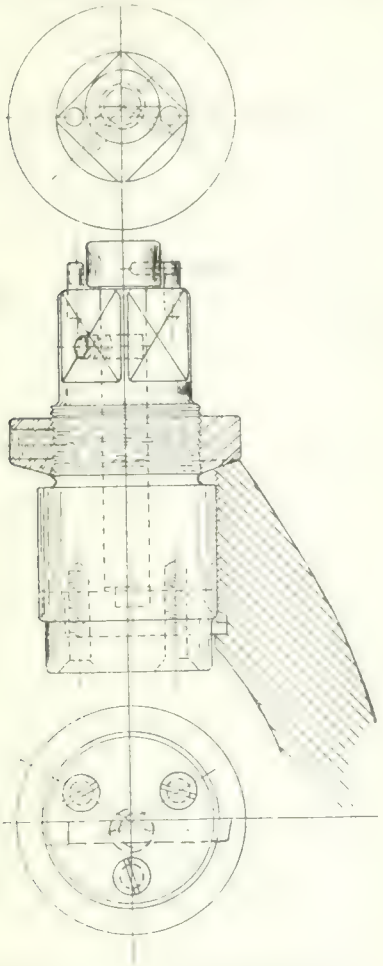
## HAND TOOL FOR SHELLS

By G. M. Dick

IN the manufacture of 6 inch shells we sometimes have a litle trouble with the distance from the bevel to the exploder



FACING TOOL FOR CONTAINER SEAT.

container seat being too short. This was sometimes caused by having to take a slight cut off the bevel to make it true with the thread. We made up a hand facing tool as illustrated to use on the inspection bench. The body is made to fit inside the thread and the pin with the eccentric end is given half a turn to push out the tool into the undercut. A wrench is placed over the square and the tool revolved until the stop nut rests on the bevel. The pin is then given half a turn back to draw in the cutter and the tool taken out.

## THE FAILURE OF HARDENED PARTS

By D. A. Hampson.

THE scrap pile tells many a story for him who reads, and none is plainer than that of broken hardened parts, such as punches and dies, forming and bending tools, etc. So many men will go right on and make new parts exactly like the old, with no real study of the reasons for breakage, blaming the trouble on the steel or the design which makes the piece so frail.

The design has only a partial bearing on the trouble. In re-making the parts it is nearly always possible to change sharp corners to filleted ones, thereby increasing the strength—often doubling it. But the greatest trouble is in making supporting sections too hard, so hard that they break at the least sideways blow or strain. Unless a part actually cuts or forms, there is no excuse for it to be hard. Every section that does not so come in contact with the stock should be drawn to a purple or a blue. The easiest way to do this on light pieces is to use a Bunsen burner.

## SPACING OF HOLES

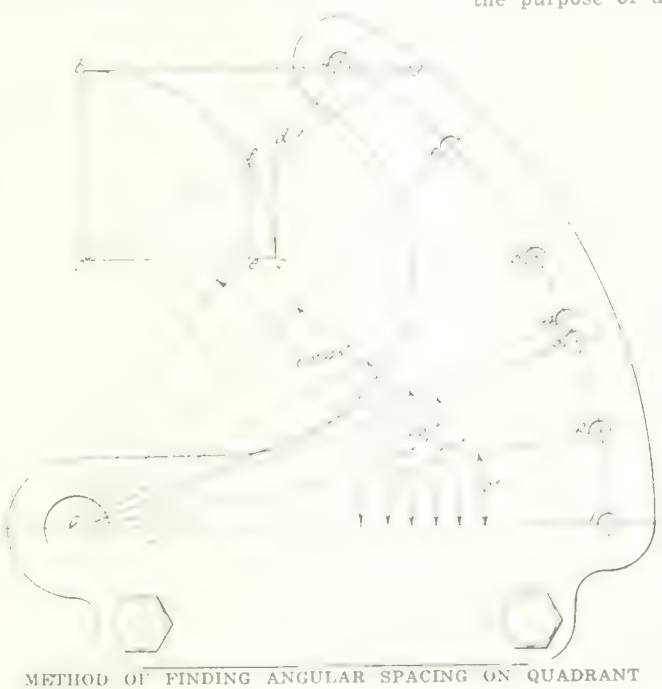
IN the spacing of holes it is often required to set them a certain distance apart on the arc of a circle so that the movement from one to another will register a definite number of degrees. In the sketch of the quadrant here shown it is required to locate several holes for graduating purposes, on the arc of a circle having a 6 inch radius, so that a lever (not shown) will revolve a shaft through the different angles indicated, namely, 10, 20, 22½, 30, 45 and 60 degrees. The simplest method to obtain the lengths of the various chords (the center distances between the holes), is by the use of the trigonometric tables which give the sines for the required angles. In the tables of trigonometric functions the values given are invariably derived from a circle of one inch radius. In the skeleton sketch above are shown the more important functions of a right angle triangle on which the tables are based, thus.

O-B equals the radius.
O-E equals the cosine of the angle.
E-F equals the sine of the angle.
C-D equals the tangent of the angle.
B-G equals the cotangent of the angle.

In order to calculate for the desired angle it is necessary to divide the isosceles triangle, formed by the two radii and the chord, into two right angled triangles, half the chord being the short side and the radius the hypotenuse. As the table values are given for a one inch radius, it is necesary to multiply these values by the radius of the specific problem to obtain dimensions required. The value for the sine of 5 degrees is given as .08716; this means that the distance E-F for an angle of 5 degrees, and the radius O-B of one inch, would be .08716 inch long; therefore, as the problem here shown has a radius of 6 inches the sine value for 5 degrees would be .08716 multiplied by 6 equals, .52296 inches. Then twice this length would equal the length of the chord, or the distance apart of the centers 1 and 2. This same process is followed for determining the chords of each angle, or the base of the isosceles triangle. The values will be found to be,

1-3 equals 2.084 inches.
1-4 equals 2.341 inches.
1-5 equals 3.106 inches.
1-6 equals 4.592 inches.
1-7 equals 6.0 inches.

It will be noticed that the last angle of 60 degrees gives a chord of equal length to the radius, thus forming an equilateral triangle 0-1-7.

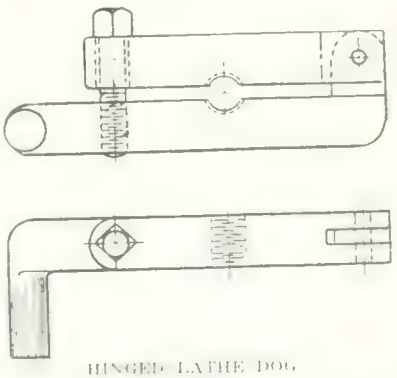


METHOD OF FINDING ANGULAR SPACING ON QUADRANT

## A HINGED LATHE-DOG

By J. E. Cooley.

A SIMPLE form of lathe-dog used for the purpose of attachng to the threaded ends of shafts is shown in the accompanying sketch. It is made from square shape stock of any suitable thickness hinged together on one end and made adjustable by means of a set-screw as shown.



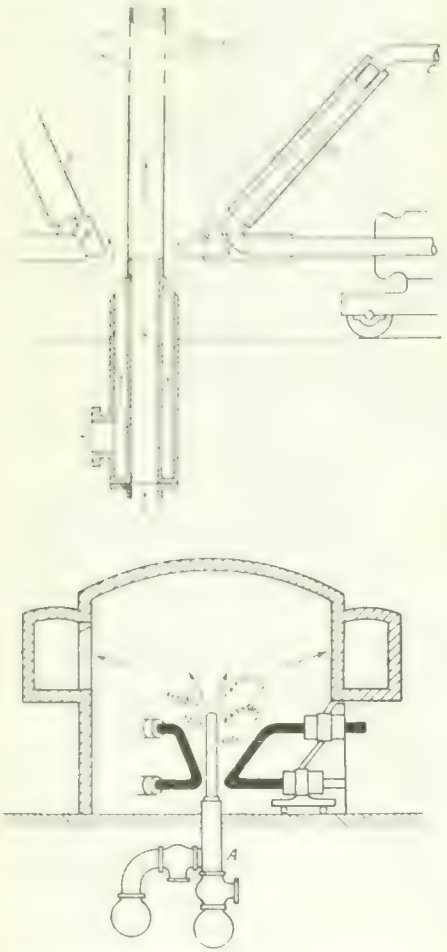
HINGED LATHE DOG

The object of the design is to save time, as in the case with most of such devices in present use in screwing the dog on the threaded portion of a shaft. It is only necessary to raise the set-screw which enlarges the hole sufficiently to allow for inserting the dog over the thread body, then clamping it down into the threads and tightening the screw.

### NEW PROCESS FOR EXTRACTING NITROGEN FROM AIR

[illegible] fixation of atmospheric nitrogen is being undertaken on a commercial scale in Sweden. The process to be employed bears the name of a well known inventor, Mr. Kilburn Scott, and depends on the action of intense electric arcs to liberate the nitrogen from the air and accomplish its fixation for commercial purposes in the form of nitric acid gas.

The operation is carried on in a special fire brick lined furnace in which



ARRANGEMENT OF ELECTRODES IN APPARATUS FOR FIXATION OF NITROGEN FROM THE ATMOSPHERE.

are mounted the three horn-shaped electrodes spaced at 120 degrees to one another and surrounding a central air supply pipe. Each horn electrode approaches close to, but does not touch, the central pipe at its lowest tip and diverges sharply upwards. The general arrangement is shown in the accompanying illustration reproduced from the patent specification.

An alternating 3-phase current is utilized, each electrode being connected with one of the supply wires. The air pipe [illegible] forms the neutral point of a star-connected 3-phase system of which the three alternating but practically continuous arc flames represent the load on the system. The arcs are driven upwards by three blasts of [illegible] from the same tube of the central pipe. The inner tube projects upwards to a point about level with the top of the electrodes and at this point there are three more nozzles supplying air under pressure. These blasts provide the cold zone which is necessary for the fixation of nitric acid gas. The air which drives the arcs upwards is preferably at a high temperature, but the air which emerges from the top of the pipe must be as cool as possible.

Due to the intense heat to which the pipe and electrode parts are subjected, provision is made for renewing parts that are liable to be burned away. The cold air pipe is surrounded by a tube which is easily renewable, and the electrodes C which are made of steel tubing through which cooling water is circulated, have renewable clips D to protect them.

The mixture of nitric acid gas and cool air is drawn off through large sized openings and passes to flues which connect with the various furnaces.

The initial installation is of 1,000 electrical horsepower capacity which will be increased if the results come up to anticipation. It is claimed on behalf of the process, that it enables nitric acid to be produced with considerable profit, the output per kilowatt year being 1½ tons, which at the prevailing prices for electric power and manufactured product leaves a good margin of profit.

### MEANS OF PRODUCING HEAT FROM ELECTRICITY

THERE are two ways of producing heat from electric energy—by means of resistance and by means of an arc—and heat can be produced for use by either of these methods from direct or alternating currents, single or polyphase and at any commercial voltage. Hence, practically all heating devices in the market can be operated from any available source of current. Of these two methods, that of producing heat by means of resistance (aptly termed the "Joulean Effect" since it is based on Joule's Law) is almost universally employed; about the only exception is that of the use of the arc in arc welding and arc furnaces.

#### Alternating Current

Moreover, due to prevalence of alternating-current supply throughout the country as well as its greater flexibility and efficiency when used over the wide range of voltages required by the various processes of application, alternating current is used in the great majority of cases. The use of the transformer with its many available taps makes possible the attainment of varying temperatures with an ease and efficiency that cannot be approached by the use of direct current, and as the heating unit load is practically noninductive and can be used in polyphase as well as single-phase circuits, the use of alternating curent for this work gives a unity power factor in almost every case and possesses many advantages over direct current. For instance, in order to obtain the low voltage used in spot welding from a direct-current supply, it would be necessary to employ a rheostat in connection with a specially wound low-voltage generator with the attendant large losses, while by the use of alternating current these voltages are readily obtained from practically any commercial supply circuit by means of the transformer.

One of the many advantages of electric heat is that it is susceptible of graduated and automatic control as to localization, time and temperature, to an extent and nicety impossible with any method of combustion. This is true whether the control be by hand or automatic, although automatic control permits of greater refinement than does hand control.

#### Control Methods

Varying heats, high, low and intermediate, are obtained with hand control by switching devices which connect the heating units or groups of units in series, in parellel or in series-parallel, much in the same manner as a four-motor street-railway equipment is handled, while if an alternating current is used, this same effect is also obtained by use of the delta-Y connection with constant voltage on the supply.

These different heats occur in certain well-defined and distinct steps according to the wattage produced by the various connections and grouping of the heating units, although in cases of small current demand, gradations between these steps can be obtained by means of a rheostat in the case of direct-current supply, and by varying the voltage on the secondary side of the transformer when alternating current is used.

In carrying on the various processes of industrial heating there is always a certain definite temperature that will produce the best results in the shortest time; which is best suited to any particular phase of the process, and it is the ability of electrically controlled units to not only meet and maintain this specific temperature to a nicety, but also to vary within a fraction of a degree with the temperature requirements of the various phases of the process, that makes the electric control stand out as superior to that employed by any method of combustion heating.—Society for Electric Development Bulletin.

**France Would Buy B.C.-built Ships.**—The agitation begun in British Columbia for the revocation of the Dominion Government's decision to disallow shipbuilding in Canada to the order of foreign interests makes the fact that ninety-six auxiliary powered schooners have recently been bought in the United States by France of special interest. It is said that if the Imperial Munitions Board would allow ships to be constructed in Canada for registry other than British, the shipyards of this Province would have no difficulty in getting plenty of contracts from French interests.

# Comparison of Working Costs of Principal Prime Movers*--II.

By Oswald Wans

*High thermal efficiency does not [illegible] ... data are seldom complete and render difficult the justification of claims and working costs advanced by advocates of respective prime movers. The engine of lower thermal efficiency may, therefore, [illegible]*

THE quantity of lubricant necessarily varies widely in practice, even in similar engines, due partly to the differences in manufacture and to the care or negligence on the part of the attendant. To cover amply these factors, the charges should be of a liberal nature.

The accompanying curves, Fig. 4, give representative consumptions for new oil, no allowance having been made for filtering and re-using the oil. The saving effected by filtering is worthy of consideration, for it is possible by this means to reduce materially the oil bill. It should be noted, however, that filtered oil cannot be recommended for use in cylinders, unless enriched by about 30 per cent. of new oil. It will be observed that as the total quantity of oil is given, it must include both cylinder and bearing oils. For internal-combustion engines, it is customary to use one grade for both purposes, whereas two qualities are usual for steam-engines in which approximately one-third of the total quantity will be required for the cylinders and that remainder for bearings, etc. The adoption of one grade of oil has a practical advantage in preventing the use of the wrong oil for, say, the cylinders, a mistake likely to have serious results in an oil or gas engine.

### Water Supply

In many localities a plentiful and gratuitous water service is not available, and the cost of the necessary supply becomes a matter of moment. With a free and suitable supply the water may be returned, directly after use, to the source, thus obviating the cost of a cooling plant. Frequently, however, the local charges render necessary a closed system whereby, with little loss, the water can be used repeatedly. For the smaller internal-combustion engines, up to 50 b.h.p., cooling tanks are very general, but for larger powers a cooler, of, say, the tower type, becomes necessary. The tower cooler is equally applicable for cooling condenser water and possesses the advantage of simplicity and low cost, but owing to its bulk is not always adaptable. When the requisite space is not available, a more costly form of cooler may be a necessity, but such cases are not general and must be considered individually.

In the Expenditure Curves, Fig. 1 (page 309), the cost of a cooling tower is included for international-combustion engines above 50 h.p. and for surface, but not jet condensing steam-engines. In the latter case it is assumed that the water is run to waste. The water lost by evaporation, in passing through the cooler, may be taken as 5 per cent. of the total water in circulation.

There may be a further loss due to leakages, but in a well-kept installation the loss on this account is negligible. This cooler loss holds good for steam-engines and internal-combustion engines, but there is a further loss in a suction-gas plant in the water required for supplying steam to the gas-producer and in the effluent from the cleaning plant. The former water is of course not recoverable, and the latter can be and is sometimes used several times before disposal. Unless special provision is made, the water is prone to foul the circulating pump and pipe-lines, and, when ultimately disposed of, is apt to arouse suspicion in the municipal mind owing to its more concentrated nature, and this applies particularly to wood refuse fuel.

Often the cleaning water can be taken continuously from and returned to a neighboring pond or river without charge. It may be remarked that the effluent after once passing through the cleaning plant is of a harmless nature, and if turned into a sewer or a river all traces of tar must be removed, as this appears to be the bete noire of local authorities.

The following table (page 108) gives the total quantity of water in service and the make-up water necessary to replace the cooler and cleaning plant losses. The latter quantities only need be considered in working costs, for the cost of the initial supply of water is negligible.

### Sundry Stores

The payments arising from these items are small, and are generally covered by a charge of 0.01d. per rated b.h.p.-hour for any of the prime movers under consideration.

### Labor

The charges under this heading should include not only the attendant's time during running hours, but also that needed to clean, grind in valves, etc., and generally to keep the installation in good condition. In the case of steam and suction-gas plants the time spent in handling the fuel and removing the ashes must be covered. The attendance time is fairly uniform for similar installations, and generally speaking is on a minimum basis. Usually it is not necessary to employ highly skilled labor, nevertheless sufficient should be paid to command the services of the intelligent

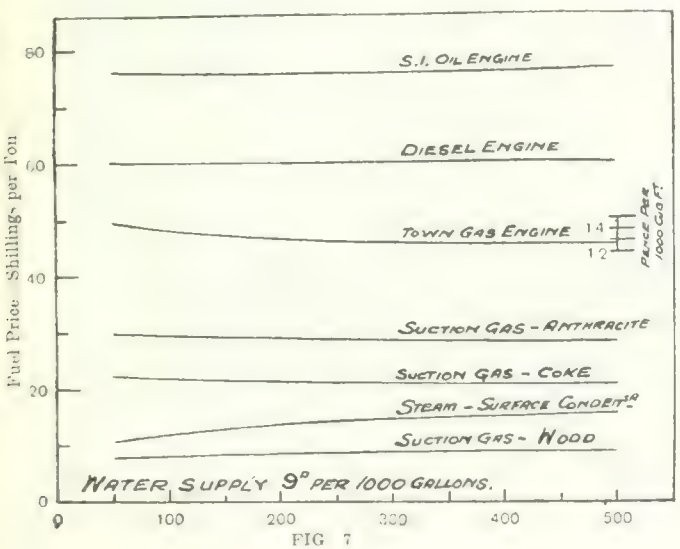


FIG. 7

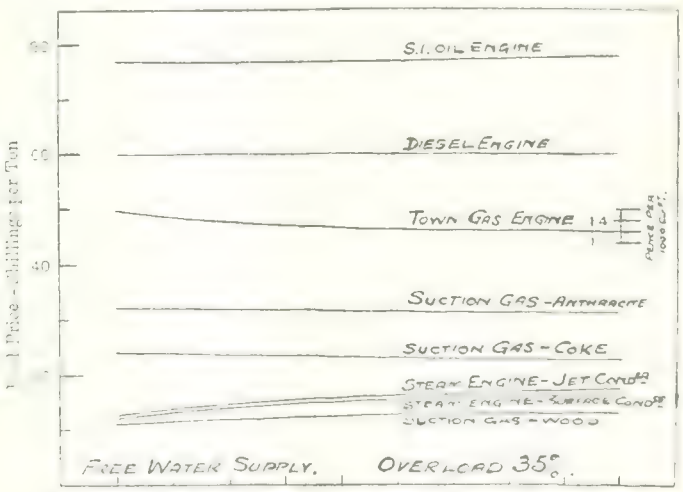

I.H.P.—Mean Working Load.
FIG. 8

*Read before the Institution of Mechanical Engineers, London, Oct. 19, 1917.

locality, due mainly to the fluctuations in the prices of water and fuel. The cost of lubricating oil and labor may vary but

*Water Consumptions.*

| | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | A | B | C | D | | |
| | 15-55 | | | | | | | $2\frac{1}{4}$-$2\frac{3}{4}$ | $2\frac{1}{4}$-$3\frac{1}{4}$ |
| | | | 0.5 | | | | | 0.325 | 0.325 |
| | | | | | | | | 0.275 | 0.275 |
| | | | | | | | | 0.375 | 0.375 |
| | | | 1.5 | 1.75 | | | | 0.375 | 2.2 |
| | | | | | | | | 0.375 | 5.87 |

The following formulae give a fair indication of the time that is spent solely upon the prime movers within the scope of this paper:—

engine plants .....0.8+0.0047 b.h.p.
Suction gas (coal and coke fuel)..0.6+0.0041 b.h.p.
S.I. and Diesel engines.....0.3+0.0036 b.h.p.

These expressions give the labor in hours per rated working load per hour. Thus for a 100 b.h.p. suction-gas plant using wood fuel, and 100 b.h.p. town-gas engine, the labor would be respectively 1.27 and 0.37 hours per hours run.

### Repairs

The annual charge should provide amply for wear and tear and such breakages as are not covered by insurance. The actual annual payment may form an appreciable portion of the running costs, and must in some cases exceed the estimated amount in view of the small provision made. This applies particularly to internal-combustion engines. There is little difficulty in citing instances of gas and oil-engines in which the repair bill over, say, 5 or 6 years, has not exceeded 2 per cent. per annum of the engine cost. Such a figure, however, should not be taken as a basis. If the cost of repairs were entirely dependent upon wear and tear, 2 per cent., there is no doubt, could be taken as a general rate.

Although internal combustion engines have proved themselves to be thoroughly reliable in service, it is nevertheless a fact that they are more prone to minor mishaps than steam engines, and due allowance must be made for a well designed gas or oil-engine, ample margin for this contingency is given by an annual charge of 3 per cent. of the engine cost.

The following are the repair charges allowed for in the Working Cost Curves, Figs. 5-6:—Diesel and S. I. oil engines, town gas engines—3 per cent. of engine cost; suction-gas installations, 3 per cent. of engine and producer costs; steam installations, 2 per cent. of engine, boiler

the annual working costs of the engines under consideration. These costs will be

not sufficiently to affect materially the annual charges. Further, the variation would be common to all installations, so that the relative working costs for practical purposes would be unaltered. The position with regard to the water and fuel supplies however, is quite different. In some districts a free water supply may be available, and in others the charge may be high, whilst the price of fuel, particularly oil, varies considerably from time to time and with the locality, thus rendering these two items almost the ruling factors of economical working.

In order to establish a relationship between the fuel prices that may be paid, and to show the influence of the water charges upon these prices, the curves, Figs. 5 and 6, have been plotted. The curves A to F, 5, give the annual charges with water at 9d. per 1,000 gallons, and in Fig. 6 it is assumed that the water supply is free, but none of these curves include the cost of fuel. The curves G represent the total annual working cost of a Diesel engine using fuel-oil at £3 per ton. It follows, therefore, the total amount that may be spent annually upon fuel to give even running charges for any one of the remaining installations is represented by the length of the ordinate between the curve G, and the cost curve of the particular engine considered. From the total fuel cost thus obtained, the maximum prices that may be paid can be easily computed, and have been plotted in curves Figs. 7 and 8, whilst the fuel prices given by those curves for plants of 250 b.h.p. mean working load are given below:—

| | Price of Fuel Curve Fig. 7 per ton | Price Ratio | Price of Fuel Curve Fig. 8 per ton | Price Ratio |
|---|---|---|---|---|
| Diesel engine.....60 | | 0.79 | 60/ | 0.785 |
| Solid injection oil engine .....76/ | | 1.0 | 76/6 | 1.0 |
| Suction Gas:— | | | | |
| Anthracite .....29 | | 0.38 | 31/6 | 0.41 |
| Coke .....21/ | | 0.27 | 23/ | 0.3 |
| Steam Engine:— | | | | |
| Wood ..... 8/6 | | 0.113 | 12/ | 0.157 |
| Jet Condenser .. .. | | ... | 16/ | 0.21 |
| Surface Conden..14 | | 0.184 | 15/ | 0.195 |
| | per 1000 cu. ft. | | per 1000 cu. ft. | |
| Town & gas engine 1/1 | | 0.014 | 1/1 | 0.014 |

In the curves, Figs. 5 to 8, the engine possessing the highest thermal efficiency, namely, the Diesel engine, has been taken as a convenient basis using fuel oil at £3 per ton. Reference to these curves shows that the relative fuel prices for the several installations are fairly uniform for the range of power under consideration. The widest variation is that shown for the steam plants due to the comparatively higher initial cost and lower thermal efficiency of the smaller powered engines. It should be noted that the fuel consumptions represented by the curves, Fig. 2, are favorable to the steam-engine and apply to compound condensing installations using superheated steam, that is to say, they are best practice figures. It may be said with certainty, therefore, that, in general practice consumptions as much as twice those represented are not unusual, thus nearly halving the fuel prices shown by the fuel price curves, Figs. 7 and 8, and further limiting the districts in which the use of the steam-engine can be defended on the score of minimum working costs.

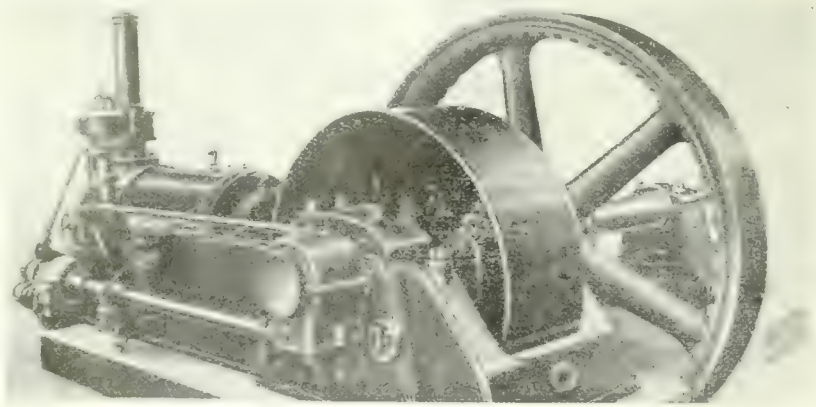

FIG. 9. SOLID-INJECTION HIGH-COMPRESSION

As the power increases a higher price may be paid for coal, and the steam-engine becomes a more serious rival of the suction-gas plant; nevertheless, for installations up to 500 b.h.p. working load the latter well holds its own, for it is possible to obtain even running costs with fuel ranging in price, according to the power, from two to three times that permissible for a steam-plant. The price allowable for town-gas is practically constant at 1s. 1d. per thousand

cubic feet, and consequently confines the use of the town-gas engine to cities in which gas is procurable at this low rate.

| | Calorific Values Assumed | | |
|---|---|---|---|
| Anthracite | 14,500 | B.Th.U. per lb. | |
| Coal (Boiler) | 13,500 | " | " |
| Fuel Oil | 18,000 | " | " |
| Wood Refuse | 5,800 | " | " |
| Town Gas | 540 | " | 1,000 cub. ft. |

Turning now to the high-compression solid injection-oil engine. A high price may be paid for fuel-oil, namely, £3 16s. per ton as compared with £3 for the Diesel engine, or a price some 26 per cent. higher, notwithstanding the higher thermal efficiency of the latter engine. The lower capital expenditure and other running charges of the solid injection-engine are responsible for this result. The future of the oil-engine must be obviously dependent upon a regular supply of uniformly low-priced fuel-oil, and it is to be feared that past irregularities in these respects have to a certain extent militated against their more extended application.

### Fuel Supply Problem

The problem of the supply of a uniformly low-priced fuel-oil is one that is well worth the serious consideration of the large oil companies, and it is satisfactory to note that during the twelve months prior to August, 1914, one company had gone a long way to establish a feeling of security amongst users of oil-engines by offering fuel at an average price of £3 per ton, and were prepared to contract for a regular supply over several years. There seems to be every probability of these conditions again becoming general after the war. An adequate supply of fuel oil, in view of the high thermal efficiency of the oil engine, is of the utmost importance to manufacturers, for it offers a means by which minimum working costs may be obtained. It is usual in the supply of electrical and hydraulic energy for power purposes, for the suppliers to charge specially reduced rates, and it is suggested that a similar procedure might be followed with advantage in the case of fuel oil.

With the fuel oil at £3 per ton, the price of coal must not exceed on the average £1 5s. and 12s. per ton respectively for suction gas and the larger steam plants over 250 b.h.p. in order that the total annual running charges do not exceed an oil-engine of the solid injection type, clearly indicating the wide field of action of this type of engine. The cheaper grades of fuel oil of not less than 0.95 sp. gravity alone are considered, as the charges of engines using the more costly and refined oils are appreciably higher and therefore commercially inferior. In Fig. 9, page 342, is shown a high-compression oil-engine of the solid-injection type, capable of handling the cheapest fuel-oils with an economy in conformity with the curves, Fig. 2 (page 309).

Considering lastly the refuse suction-gas plant, the price of the fuel ranging as it does from 11s. to 13s. per ton, even with a free water supply, limits its use to industries in which the wood or other refuse mentioned below is a waste product of the industry, for it is seldom possible to obtain a constant supply at these rates. Under this condition refuse installations are unquestionably the cheapest form of power. The illustration, not shown, shows the producer of a 300 b.h.p. suction-gas installation working entirely upon sawdust, shavings, wood blocks, etc. A producer of this type will also handle such refuse fuels as various kinds of husks and nut shells ,bark, spent tan, plum stones, etc.

The use of suction-gas as a heating agent is yet in its infancy, but very satisfactory results have already been obtained in laundries, woodwarking factories, tinsmiths' shops, etc. The gas is drawn from the producer through a purifier and pumped to a gas-holder, from which it is piped under slight pressure to any part of the factory, and by the aid of an air-mixer and burner used in a similar manner to town-gas. This feature is worthy of consideration, for it adds to the general utility of the suction-gas installation, and may in some cases effect an appreciable economy in the working costs. The plant, supplies gas for heating purposes in addition to that required for power. The possibilities of the system suggest many applications in which economies could be effected.

An objection sometimes advanced against the adoption of the internal-combustion engine for certain classes of works as, for example, tanneries, laundries, cotton mills, factory heatings, etc., is its inability to provide a steam-supply. This difficulty has, however, been met to a large extent by the exhaust heated boiler which is capable of supplying about 2 lb. of steam, from and at 212° F. per b.h.p.-hour of the engine. The steam being generated from the exhaust heat that would otherwise be wasted may be truly stated as costing nothing beyond the small additional charges due to depreciation and interest upon capital. The illustration, Fig. 10, herewith shows a boiler working in conjunction with a 250 b.h.p. suction-gas engine, and is capable of supply about 500 lb. of steam per hour, which is equivalent to the saving of 65 lb. of coal per hour.

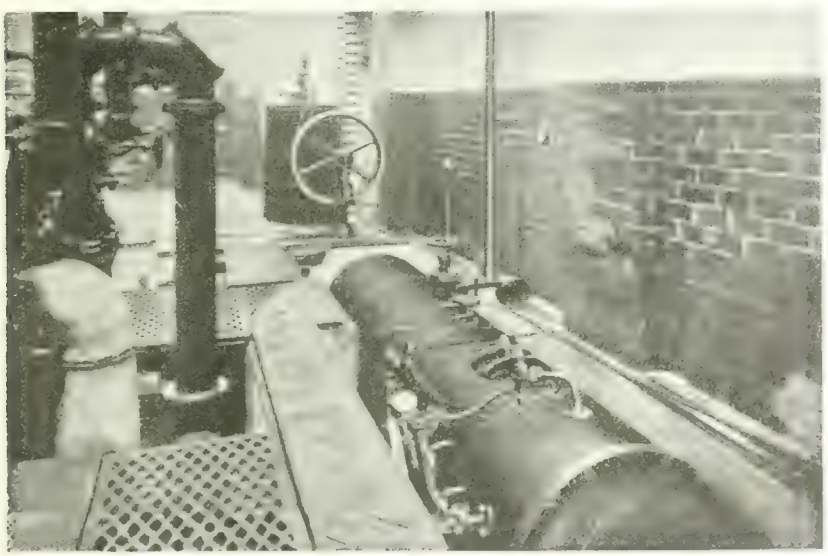

FIG. 10. BOILER HEATED BY EXHAUST FROM 250 BRAKE HORSE POWER SUCTION-GAS ENGINE

### Conclusion

It is evident from the foregoing that statements to the effect that a certain class of engine is the most economical requires qualification. It has been shown that the cost of fuel has a deciding influence upon the working cost, although that due to the necessary water-supply may be serious in some districts. Now, as the cost of fuel is regulated largely by railway and shipping freights, it is clear that the distance from the source of supply has an important bearing upon the kind of fuel, and it follows the type of engine that should be installed.

The maximum permissible prices that may be paid in any locality are indicated generally by the ratios giv more particularly by the curves and 8 page 341. The application of these price rati that each type of engine has its lar field of action in which it can be used with commercial advantage, provided due regard is paid to the local conditions, or in other words, an exclusive claim to minimum working costs cannot be rightly made on behalf of any one of the prime movers under consideration.

The relative fuel prices do, however, indicate that the scope of the steam-engine is less than the oil-engine, for in the best practice of the former the price of coal for the larger installations of 250 h.p. and upwards may not exceed on the average one-fifth of the price of fuel-oil for an engine of the solid injection type and one-fourth for Diesel engines, and appreciably less for smaller powers. Between these extremes stands the suction-gas plant, for which the price of coal and coke may be respectively twice and 1½

It is obvious, therefore, that the commercial superiority of a prime mover is [illegible] mal efficiency, but by the local conditions regulating the price of fuel. From the purely engineering point of view this is not entirely satisfactory in that, however thermally efficient an engine may be, the ultimate test is a commercial one involving the market price of fuel, which [illegible] from the commercial standpoint.

The whole problem is one that cannot but force itself more and more upon manufacturers with the keener competition that may be expected in the near future, and unless correctly solved must tend to handicap any industrial concern as the result of the higher establishment charges that must necessarily follow. The right solution not only benefits the manufacturer, but also affects an economy in the national resources by preventing the waste of fuel so frequently met with in practice, suggesting that minimum costs are either not sought or that the regulating conditions are not fully appreciated by those responsible.

## WELDING OF LOCOMOTIVE FIRE BOXES

THE importance of oxy-acetylene and electric welding in relation to the iron and steel industry was amply demonstrated at the December meeting of the Canadian Railway Club in Montreal, when the subject of the evening was a paper on "Oxy-Acetylene and Electric Welding and Cutting Processes in Locomotive Works." The subject matter of the paper, (a reprint of which appeared in a recent issue of this publication), dealt largely with the application of these two processes as practised at the Point St. Charles shops of the Grand Trunk Railroad. While the paper in itself was of a highly interesting character, it was the discussion that followed which impressed all present with the rapid development and growing importance of this method of construction and repair in relation to locomotive and marine activity.

While the ever widening scope of this art was recognized and appreciated by those present, it was its adaptability to firebox work that brought forth the interesting and instructive arguments [illegible]

The point or points, upon which the discussion revolved were the debatable used in places where these joints would be exposed to the excessive heat of the fire on the one side and subjected to the high steam or water pressure on the other. From the statement of Mr. Dyer it is interesting to note that the Stratford shops use the oxy-acetylene process, while the electric process is the one adopted at the Montreal shops; the method in either case for general purposes being the butt welded joint. Apparently, considerable success has been attained from the butt welding process, as gathered from the experience of the Grand Trunk officials.

### Prefers Lap to Butt

In direct contrast to this, however, Mr. Barry, of the St. Lawrence Welding Company, stated, that after a lengthy period of practical experience in the handling of firebox work, of a wide and varied character, it was his firm opinion that, irrespective of the process used, the lap weld was to be preferred over that of the butt weld. He also stated, however, that a satisfactory job might be accomplished by either methods, according to the skill and ability of the operator; but that this was a factor so uncertain that no guarantee could be given, even by the most experienced operator, that the weld was "perfectly sound."

He cited an instance where a tank head had been welded by the oxy-acetylene process by means of the butt method and had stood a test of 50 per cent. over the working pressure without the least sign of a "weep." Nevertheless, after being three weeks in service the head suddenly blew out, and upon examination it was found that, while the external appearance was in every respect perfect, the weld had not been made through the entire thickness of the plate. The head had come away so suddenly that no previous warning was given, but fortunately no one was hurt. Mr. Barry contended that had this been a lap joint, with the pressure tending to keep the surface in contact, that the head could not have come away before first giving some warning. He said "The factor of safety is something that cannot be overlooked. The question of safety is much more important than a firebox going out of service."

Apart from the advisability of using either method of weld, the problem of the man operating the blow pipe is probably the all-essential factor in the successful accomplishment of oxy-acetylene welding; the same also applying to the manipulation of the arc in the electric process. In speaking on the ability of the operator to do efficient work, Mr. Royer of the Welding and Supplies Company said, "One of the principal drawbacks in connection with the process of oxy-acetylene welding is the long time it takes to educate men to weld properly. A poor operator is liable to either stick the added metal to the plate or to burn the metal, and it takes time for the men to properly handle the blowpipe so as to neither get adhesion or burning, and to judge the correct temperature when to start the weld."

### Need of Trained Men

A common fault of the beginner is to keep the flame of the blowpipe playing too long in one particular spot, thus localizing the heat and preventing the proper fusing of the adjoining metal, with the additional possibility of burning the steel or other material. The flame of the blowpipe should be kept continually moving with a slight elliptical motion, so as to distribute the heat evenly at the portion being welded. Speaking further, Mr. Royer said, "There is no doubt that a considerable amount of boiler work can be done very satisfactorily, if the men are properly trained, however, discrimination should be exercised in boiler work, in using only reliable welders on jobs where failure would be dangerous, and apprentices and beginners can be used on those parts where failure will not produce accidents. If a shop could get efficient welders, it would save thousands of dollars in maintenance costs."

Mr. Buckland of the C.P.R., speaking on the effectiveness of the weld in relation to the ability of the operator, said "A blacksmith will not take a piece of metal and try to weld the tip of it to the tip of another piece. He wants the metal properly heated to produce a successful weld. I think we should pay more attention to selecting good men for this class of work. If you are making a weld in a firebox on a long narrow strip, you localize the heat along that weld and it cools rapidily, and there must be an initial strain on that weld, which should, to my mind, be removed by slight annealing after the weld has been made." This brought out the fact that in the repairing of marine boilers in Europe, the practice of hammering the weld with a small hammer, immediately after the weld had been made and while the metal was still redhot, was extensively adopted. This was intended to take the place of the rolling process to which the plate was originally subjected. Following this hammering process the entire welded portion and its surrounding parts are annealed by bringing it and the adjoining sections to a cherry red by means of the blowpipe. By this method it has been claimed that the strength of the joint would be increased from 85 to 95 per cent. of the strength of the plate.

### Clean Metal Essential

One of the objectionable features in reference to lap welding, as emphasized by Mr. Buckland, was the extreme possibility of the presence of scale on the sheet, which if not previously removed would undoubtedly result in a very poor weld. To overcome this it would be necessary to take off all the scale and see that the sheets are properly prepared.

In answer to a question from one of the members in connection with the improvements that had been made in getting away from the double thickness of

metal, on or adjoining the fire line, Mr. Barry said, "We do not put patches in fireboxes that come in line with the fire. Anyone who does that should not be allowed to use the boiler. The reason is that the fire causes such an amount of expansion and contraction that the weld cannot last. You have to get above the fire line a foot or more, and the higher you get above the fire line the better the patch will hold. Any weld alongside of the fire line is going to burst sooner or later—generally sooner."

### Educational Research Needed

With the process of oxy-acetylene and electric welding occupying such an important position in the metal working industries it would appear that the time is opportune for the formation of some form of research bureau to thoroughly study the many questions that are involved in this comparatively new but rapidly developing science, with the purpose of putting the practice on a more certain basis regarding the efficiency of the work and the education of the men that are necessary for the production of reliable and satisfactory work. At present the art is greatly curtailed owing to the lack of knowledge on the part of the majority of operators regarding the fundamental principles pertaining to the technical characteristics of the processes. It would also appear that for men to become thoroughly efficient at this work they must acquire considerable knowledge pertaining to the physical nature of the different metals upon which they are required to make welds. The chemical reaction that must necessarily accompany the fusing of the two metals and the addition of the filling rod must change the nature of the weld from that of the metal in the body of the plate or object being welded, and it is this change that eliminates the possibility of placing a known factor of safety on this particular class of work.

## U. S. GOVERNMENT RECOGNIZES RESEARCH WORK OF COLLEGES

THE attitude of the U. S. Government in respect to enlistments of engineering research students is revealed in the ruling of the office of chief engineer, as recently announced by the United States Bureau of Education.

The new regulations permit of all resident graduate students in engineering who are candidates for an advanced engineering degree being placed on the inactive list until they have completed their educational training. In the interim they shall be registered as enlisted in the Enlisted Reserve Corps of the Engineer Department.

This ruling would indicate that the Government recognizes the importance of research work to the future welfare of the nation, and is taking steps to foster and encourage the more extended establishment of research fellowships in colleges and universities.

The Engineering Experiment Station, as established by the University of Illinois in 1903, maintains fourteen of these research fellowships, tenable for a period of two consecutive years. These are open to graduates of approved American and foreign universities and technical schools, and carry an annual stipend of $500. Not more than half the time of the Research Fellows is required in connection with the work of the department to which they are assigned, the remainder being available for undergraduate study, and at the end of the course, if all requirements have been met, the degree of Master of Science will be conferred.

Research work is undertaken in architecture, architectural engineering, chemistry, civil engineering, electrical, mechanical and mining engineering, municipal and sanitary engineering, physics, railway engineering and in theoretical and applied mechanics. In all these various branches of engineering investigations are carried on in problems of importance to engineers and to the manufacturing and industrial interests of the State.

## ELECTRIC LOCOMOTIVES MAY SUPERSEDE STEAM

Actual want of any commodity provides the most direct appeal possible for its conservation. The use of electricity, instead of steam, on those portions of Canada's railways adjacent to water-powers would materially reduce our dependence on the United States for coal. In 1916, the railways of Canada used 8,995,000 tons of coal, or about 61 per cent. of our total production. A writer in "Conservation" remarks that the increased price of coal may soon compel us to use hydro-electric energy extensively as a railway motive power.

Certain American railway companies have carried out extensive experiments in electrification within the past two years and many of the results are of more than ordinary interest. On its Rocky Mountain division, the Chicago, Milwaukee & St. Paul replaced its steam locomotives by electric. Electricity is decidely superior to steam in operating efficiency, especially in cold weather. Electric power made it possible to operate more trains over the same tracks and that, without the need for "helper" locomotives. Again, there was a great saving in terminal and round-house facilities, and the rolling stock was not subjected to as much wear and tear as when steam was used. This latter fact was largely due to the superior braking qualities of electric-drawn trains. Air brakes were not used on grades, except in cases of emergency. In fact, it was found that as much as 11.3 per cent. of the power consumed during the period of the test was generated by the trains themselves on the down grades. The experiment was so satisfactory that the company has decided to instal electric equipment on its Cascade division as well.

In a region so lacking in coal and so rich in water-power as is Central Canada, we may expect that, in time, the increase in the cost of coal will, in favorable situations, induce the electrification of part of our steam railway mileage. If the coal now consumed by railway locomotives could be turned to other productive uses, an important step would be taken in making Canada more independent of the American coal market. Concurrently with that advantage, the country's trade balance would be considerably improved.

## MARKET FOR WOODWORKING MACHINERY IN ITALY

A United States Consular report has the following to say in regard to the woodworking machinery market in Italy:

The use of woodworking machinery in Lombardy (consular district of Milan), is extensive. In fact the woodworking industries are well developed, the most important being furniture, doors, blinds, carriages, automobiles, other vehicles, frames, mouldings, fixtures and planing-mill products. These machines are almost exclusively supplied by other countries. Only one plant in Italy turns out woodworking machinery. It is in Mondovi, Piedmont, and supplies only 5 per cent of the total trade. Before the war, 70 per cent was supplied by Germany, while the other machines sold were French, American and Italian.

The fact that only a few American machines were sold in normal times is explained by the keen competition of the German manufacturers, and their favorable prices and terms. One concern offered terms on the basis of instalment rates up to three or four years.

The present demand for woodworking machinery for the private trade is limited as several factories are closed. On the other hand, important sales are made to the Government. Offers to the Italian Government, it is understood, are to be addressed to its representatives in America.

The user of woodworking machinery rarely orders the machine direct from the manufacturer, especially when he is not thoroughly acquainted with it. The business is handled by representatives in Milan. American machines are usually sold here through general agents in London and Paris. Before the war only machines for making wheels and blinds were sold. The dealers here state that the best method of increasing the sales [illegible] by appointment of general Italian agents in Milan.

Both native and imported lumber is used in Lombardy. The wood grown in Italy is oak, elm, chestnut, olive, ash, cherry, maple, poplar, fir, pine, larch and linden, while the varieties imported are mahogany which is received from Cuba, Porto Rico, and Honduras; cedar, from Brazil; ebony, sycamore, etc., from Africa; and poplar, pitch-pine, fir, and oak from the United States and Canada.

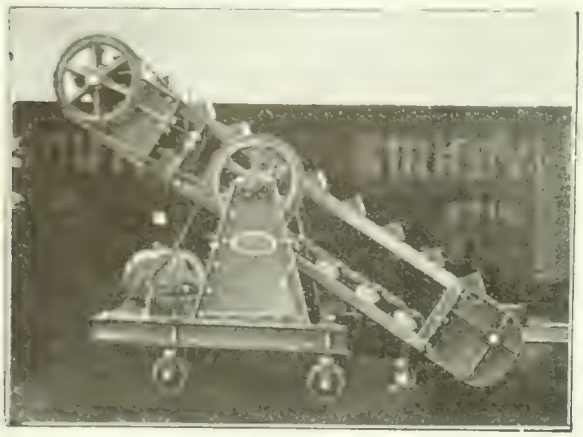
[illegible] weighing over 300 kilogrammes is 9 lire gold per quintal. When prices are quoted, they should be accompanied by actual freight rates to Genoa. Catalogues should be printed in Italian.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

### A PORTABLE ELEVATOR

MANY [illegible] in handling the handling or transport of materials could be performed with [illegible] and other [illegible] a large saving in labor, but in many of these cases the installation of a fixed or elaborate conveying system would not be practicable or justifiable, owing to the changing venue of operation or the irregular, possibly infrequent, and not always calculable periods when its use would be required. Such conditions are admirably met by the use of portable elevators or conveyors. They can be brought into use as and when required; they can be moved from place to place with the greatest ease, and they can be arranged so that the work of loading and unloading can be carried out by merely reversing the running.



PORTABLE COAL ELEVATOR.

The accompanying engraving shows a small portable coal elevator of this type which is manufactured by the firm of E. Bennis & Co., Bolton, Lancs. It is 10 ft. long between centres of the drums and has buckets 8 in. wide.

[illegible] mounted on a portable truck in such a manner that the angle of the elevator can be altered if desired. The truck is built out of mild steel sections and is carried on four rollers. All the rollers are attached to pivoted axles. [illegible] a square so that it can be turned round with a spanner, and provision is made for locking the wheels in four positions. The elevator is driven by two chain drives. Two sprocket wheels are placed on the pivot shaft. One of these sprockets is driven direct from the motor, and the other sprocket drives the elevator shaft, so that the relative centres of the shafts are maintained irrespective of the angle of the elevator. When in operation, the elevator is pushed up to the coal heap, and the coal trimmed forward to the buckets.

### BALL BEARING LATHE CENTRE

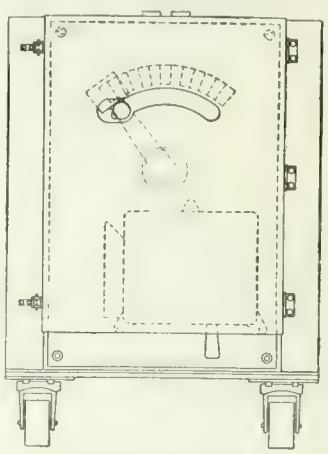
THE accompanying illustration shows a type of ball bearing lathe centre which has been designed by J. A. Moller, New Rochelle, N.Y. It consists of a revolving stem centre and conical bearing, which latter is threaded to screw into the housing and is adjustable in the housing with a lock ring. Located in the centre of the stem is a tri-thrust ball bearing which transmits the end thrust from the stem to the housing and allows the stem to revolve freely and with the least friction. This feature will commend the use of the ball bearing centre in high-speed engine lathe production work.

Positive oil supply is secured by providing a large oil chamber in the housing, which may be filled with oil by removing the headless set screw shown in the cut. Channels and drip retainer provided in the cone bearing allow the oil to circulate freely and ensure a liberal supply of oil to the bottom of the bearing. The ball thrust bearing is supplied with oil by a central oil duct cut in the housing.

The shank is in one piece with the housing, and is supplied with an extension rod for knock-out, which can be cut to different sizes as required. This centre is also made with stem bored to receive differently-shaped points as shown in the illustration to the right.

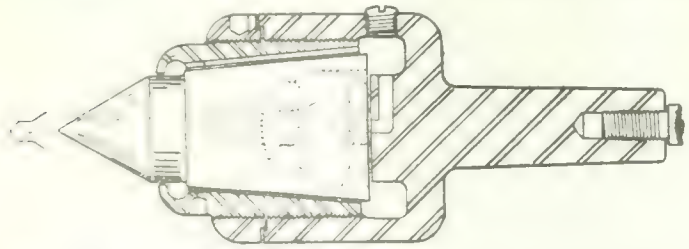
### PORTABLE OUTLET PANELS FOR ELECTRIC WELDING SERVICE

FOR an electric welding outfit to be of its maximum service, it must be so arranged that it can be taken to the work no matter where it may be located. For instance, in a railroad shop there should be outlets adjacent to each stall in the roundhouse, one or more on the washing tracks outside and others in places through the shop. In a boiler shop there should be an outlet on every other column and in a large machine shop there should be an outlet adjacent to each of the larger machines in order that work may be done in filling up blow holes and other defects on large castings with the minimum amount of crane handling.

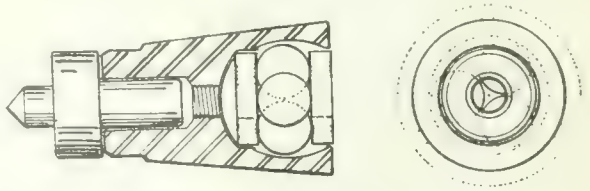


PORTABLE OUTLET PANEL FOR ELECTRIC WELDING SERVICE

One solution of the problem would of course be to locate a panel outlet of a suitable type wherever it is anticipated that electric welding might be desired. However, this is rather an expensive proposition and many electrical engineers would prefer to accomplish the same result in a simpler manner. The accompanying engraving shows a recently developed portable outlet manufactured by the Westinghouse Electric and Manufac-



[illegible] WITH CONICAL ADJUSTMENT [illegible] WHILE RUNNING



SECTION OF CONICAL STEM WITH POINT BORED OUT TO RECEIVE INTERCHANGEABLE POINTS TO SUIT VARIOUS CLASSES OF WORK

turing Company which takes care of this situation with a minimum of expense and with all the simplicity of the familiar distributing system for storage battery charging.

Two types of portable outlet panels are furnished, both being mounted on light trucks. They consist of a control panel mounting a handle trip railway type circuit breaker having overload release with magnetic blowout, and a 13-point face plate connected to a resistor mounted in the rear of the panel. The face of the panel is protected by a metal cover through which the handles of the rheostat and circuit breaker project. The resistor is made up of grids and is protected by a cage of expanded metal. Type E panel is intended for metal electrode welding, only, having a capacity of from 80 to 170 amperes. With this outfit one metal electrode holder and one shield are supplied. For a wider range of work a Type F panel should be used. This will handle metal electrode work from 80 to 160 amperes, and light graphite electrode work up to 300 amperes. The outfit includes one metal electrode holder, one graphite electrode holder and one mask.

In installing an electric welding system using these portable panels, the best method is to place the arc welding motor generator set at some central point. Where suitable low resistance ground connection can readily be made throughout the shop, as for instance, where metal floors or cast iron bedplates are in general use or in a railway shop where the track system can be used, only one connector need be extended to the various receptacles. The iron floor plates may be arc-welded to each other and isolated sections tied together by an iron rod or heavy copper cable, while the track rails may be bonded by arc-welding the fish plates to the rails. Receptacles should then be provided at suitable points throughout the shop of a capacity appropriate for the service for which they are intended. These receptacles may readily be mounted out of doors if they are provided with protection from the weather. Only single pole receptacles and a single wire cable to the portable panel need be provided. This cable should be of sufficient length so that the panel may be placed as near as possible to the work in order to save steps and valuable time for the welding operator. The flexible cable leading from the panel to the electrode holder should be as short as is consistent to the class of work to be done.

Where metal floors or tracks are not available, the ordinary two-wire system of distribution with double-pole outlets and two-wire cables should be provided.

## CIVIL ENGINEERS CHANGE NAME

THE final session of the 32nd annual meeting of the Canadian Society of Civil Engineers, held in Montreal, which closed on Jan. 23, proved to be the last held under that name. When the voting came, it was found that a very large majority of the members were in favor of changing the name to "The Engineering Institute of Canada."

Following this came the election of officers, when H. H. Vaughan, vice-president and managing director of the Dominion Bridge Co., was elected president, to succeed J. S. Dennis.

The following officers were also elected vice-presidents: T. H. White, Vancouver; J. M. R. Fairbairn, assistant chief engineer of the C.P.R., Montreal; Prof. H. E. T. Haultain, of the University of Toronto, and R. F. Hayward, of the Western Canada Power Co., Vancouver.

Past presidents—F. C. Gamble, Victoria, B.C.; G. H. Duggan, Montreal; J. S. Dennis, Montreal.

Council—J. R. Ambrose, Toronto; N. E. Brooks, Sherbrooke; Prof. E. Brown, McGill University; A. R. Decary, Public Works Department, Quebec; H. Donkin, Halifax; A. E. Doucet, Quebec; Walter J. Francis, Montreal; Prof. P. Gillespie, Toronto University; J. H. Kennedy, Vancouver; C. D. Lafleur, Ottawa; D. D. Lewis, Victoria; H. Longley, Woodman's Point, N.B.; G. A. McCarthy, Toronto; D. H. McDougall, general manager, Nova Scotia Steel Co., Sydney, N.S.; E. G. Matheson, Vancouver; L. A. Thornton Regina; John Murphy, Ottawa; J. M. Robertson, Montreal; Jas. White, Ottawa; Wm. Pearce, Calgary; D. A. Ross, Winnipeg; R. A. Ross, Montreal; H. R. Safford, Montreal, and Julian C. Smith, general manager of the Shawinigan Water & Power Co., Montreal.

## WILL INCREASE COAL PRODUCTION

THE War Committee of the Cabinet, Ottawa, has decided to take steps to increase the coal production in Eastern Canada, and in that connection the most recent returns show that the present output is [illegible]. It is practically all from Nova Scotia, and while there are collieries at Springhill, Stellarton and Inverness, the great percentage of production is from the mines in and adjacent to Sydney. As the seams are already developed the problem of augmenting the output is largely one of securing the necessary labor. Recently some unrest among the miners was reported and a member of the Government went down to Sydney and squared away matters. Any dispute will be referred to arbitration. If sufficient men can be secured at least a 50 per cent. increase in output [illegible] for by next season.

By way of more immediately relieving the situation, there is a probability of curtailing the operation of some of the less important industries down East, and diverting westward part of the coal in their bunkers.

## B.C. MANUFACTURERS WANT MORE WAR ORDERS

AT A meeting of the British Columbia Manufacturers' Association held in Vancouver last week, strong exception was taken to the action of the Dominion Government in not giving a fair proportion of war orders to the west coast province, it being stated that during the four years of war, not more than $20,000,000 out of a total expenditure of $1,800,000,000 in contracts had been given to British Columbia manufacturers, exclusive of the shipbuilding program. As a remedy it has been proposed that the various municipalities in the province unite in sending a strong man to Ottawa and keeping him there until what is considered a fair share of this business makes its way to the coast.

In the course of an address before the members of the association President Cunningham stated that it had been a considerable time since any commercial war orders had been received in the province with the exception of a few small orders for food supplies, although strong representations had been made to headquarters in Ottawa. While Vancouver firms had tendered for the supply of boots, he said that [illegible] lotted to Quebec. The recently-elected B. C. members of the Dominion House will be approached on the subject of war orders and these men on arriving at Ottawa for the session of the House will be asked to make insistent demands that a more equitable division of contracts be made.

## MATERIAL FROM U.S. FOR SHIP BUILDING

ARRANGEMENTS have been made, it is understood, whereby a supply of ship plates and steel shapes for the construction of the first vessels to be laid down under the Dominion Government's recently announced shipbuilding programme will be procured from the United States. In view of the present lack in Canada of facilities for the rolling of such material, it was necessary to enter into negotiations to obtain it from the United States. Alex. Johnston, Deputy-Minister of Marine, and Charles Duguid, the naval architect of the department, have been in Washington to discuss the question with the United States authorities. They were assisted in their negotiations by Sir Charles Gordon, formerly of the Imperial Munitions Board, and now of the British Purchasing Commission in the United States. They are stated to have been successful in making arrangements, details of which have not yet been made public, but which are said to be satisfactory to the Government.

Most of the shipyards of the Dominion are occupied at present. Ships now under construction, however, will be launched from time to time, beginning about June. It will then be possible to lay the keels of the first of the Government's projected standardized merchant fleet upon which an expenditure of some sixty million dollars annually is contemplated.

In order that British and Canadian requirements may be met it has been decided that no further orders for ships other than for British or Canadian registry shall be taken in the Dominion. At present there are some vessels being constructed under Norwegian orders.

## MORE STEEL AND LESS INSPECTION?

MORE than ordinary importance attaches to the conference which took place last week at Ottawa between the leading steel makers of Canada and the War Committee of the Cabinet. Following the conference, the announcement was made that an increase of from 20 to 25 per cent. in steel production had been promised by the steel men, provided the raw materials are available as usual.

The extent to which this proviso may become necessary would seem to depend on the degree of co-operation which the Imperial authorities are disposed to extend to our steel makers. That the steel makers should feel confident enough of their ability to promise such an increase is sufficient proof in itself that they realize the urgent need for more steel, a need which becomes more and more pronounced as the United States program develops, with the possibility of future restrictions on supplies from that source.

The nature of the proceedings would seem to indicate also that, in the eyes of the Imperial authorities, Canada's own needs must be entirely subordinated to their demands. No Canadian with the welfare of the Empire at heart will hesitate to make sacrifices when necessary; indeed the actions of many prominent men in all walks of public life have demonstrated their willingness to meet such conditions; the question of just how far such an understanding should influence and control the industrial and manufacturing activity of the Dominion is a point, however, regarding which Canadians themselves should be allowed a reasonable degree of self assertion.

The railways are not only overburdened with traffic in excess of all previous records, but have to handle this [illegible] with decreased equipment, depleted staffs, lessened [illegible] many vital grades by the call for military service, and [illegible] accelerated track conditions which are fast approaching the critical point.

In other words, the ability of the country to produce and handle the requisite volume of business to insure economic conditions necessary to its continued participation in the war will soon be, if it is not now, just as dependent on internal trade conditions as on munitions output; or, to express it differently if more cogently, we can not burn the candle at both ends and get all the light at one end.

If munitions must be produced at all costs the manufacturers of the country ought to know it, but the country ought not to be made to suffer through the inordinate and over-exacting demands of an officialdom thousands of miles away.

The question of what constitutes inspection has been a live topic both with steel makers and shell manufacturers ever since munitions came to Canada, and the extent to which a rigorous, unbending, and what is claimed to be a blindly applied system may seriously interfere with the efforts of producers is, we believe, great enough and vital enough to warrant instant and complete recognition from those in authority at Ottawa who are qualified to present the true state of affairs to the British War Office.

Those familiar with the efforts of our steel makers know that they have done everything humanly possible to increase output and overcome initial defects. During the past three years they have not hesitated to spend money lavishly to increase output and maintain quality, and as experts in their own business are entitled to more than ordinary consideration when they claim that, if intelligently applied, the present requirements of the Imperial authorities could be easily met, and the required increase of 20 to 25 per cent. obtained through a reduction of discards.

The question of just how far any particular defect interferes with the acceptability of an ingot or bar of raw material has been pretty conclusively decided by eminent metallurgists, especially in England. Certain marks known as shadows or ghost lines were very fully investigated during the early stages of the war by one of those specialists, and while, to the best of our recollection no definite decision was arrived at regarding their cause and effect, their influence on the metal was not considered sufficiently detrimental to justify rejection. That this decision deserves full consideration is shown by the report that such material is accepted in the United States, and they, according to Secretary Baker's statement before the Senate War Committee, Monday, were advised by British experts what to do and what not to do.

The necessities of the moment are pressing. High costs compel efficiency on the part of the manufacturer. Specifications containing stated conditions are also efficient if applied with a due knowledge of conditions and appreciation of results involved. Engineering leaders as a class are probably the most honest of producers as their product can be judged from a purely scientific standpoint with no human element entering thereinto. But in order to judge such product a fair knowledge of the science involved is desirable.

The personnel of the inspection staff in many parts of Ontario at least has not conformed to this primary requirement, and the report that such non-technical and unscientific fields as real estate, insurance, window-trimming, etc., have been utilized as recruiting grounds for inspectors casts more than a passing shadow on the various government departments and officials involved, whether their acquiescence has been active or passive.

# INDUSTRIAL NOTABILITIES

NORMAN ALAN HILL, general manager, Carriage Factories, Ltd., Excelsior Life Building, Toronto, was formerly consulting efficiency engineer to Berger Mfg. Co., Canton, O.; Stark Rolling Mill Co., Canton; Canton Culvert & Silo Co., Canton; B. F. Shaw Co., Wilmington, Del.; Arlington Co., New York, as well as various shipbuilders, engineers and allied firms.

Mr. Hill was born in Baltimore, Md., Sept. 7, 1882, son of Thomas and Harriet Louise (Westcott) Hill, and received his education at the Friends' School, Baltimore;

NORMAN ALAN HILL

West Jersey Academy; Lafayette College; graduating from University of Pennsylvania (B.Sc., 1904); post-graduate, Pennsylvania University and Columbia University (Mechanical and Electrical Engineering).

In March, 1912, he came to Canada, and practised industrial engineering until Sept., 1914, when he returned to Baltimore; on Oct. 1, 1917, he was appointed general manager of Carriage Factories, Ltd., of Toronto and Montreal, with two factories at Brockville, one at Orillia, one at Montreal, and one at Alexandria.

Mr. Hill is a member of the Society of Industrial Engineers, and as such has made reports, etc., for the Council of National Defence of the United States.

He married Emily Turnbull, daughter of John Nunn Heflebower, Dec. 11, 1907, and has two sons.

His club membership includes the Beta Theta Phi Fraternity Club, of Philadelphia, and his recreations are motoring, motor-boating and boxing.

Mr. Hill's residence is 24 Douglas Drive, Toronto, Ont.

# Ship Plate and Shapes Assured for Government Vessels

*[illegible] severe weather continues—Official statement awaited regarding size of ships to be built by Government—Steel prices unchanged generally —Machine tool trade quiet*

**The [illegible] severe weather continues to adversely affect the railroads and little headway can be made in relieving the freight congestion until conditions improve. Prevailing conditions are restricting manufacturing operations and production is being curtailed. Supplies of coke continue deficient and steel companies are unable to operate at full capacity. The cold weather is also affecting operations at the mills. It is understood that the Government has been assured of a sufficient supply of plates and shapes for the first vessels to be constructed under the new program. No official statement has been issued in regard to the size of the ships to be constructed but it is reported that arrangements are being made for keels to be laid down some time in June. Existing shipyards will be utilized for the carrying out of the Government program. Nothing further has been said regarding the proposed plate mills being established in Canada, but it is not unlikely that action will be postponed in view of the fact that plates can be obtained in the States. There have been no changes in prices of steel products this week. There is no improvement in the pig-iron situation, the freight congestion and severe weather continue to hamper operations at the furnaces. The scrap metal market is quiet and quotations are unchanged. The fixed price of copper, in the States, at 23½c per pound, has been extended until June 1st. This has caused some disappointment in the trade as it had been hoped that the price would be advanced to 25c in order to stimulate production. The tin situation continues acute with no relief in sight. Prices of all non-ferrous metals are unchanged. The machine tool trade has been rather quiet this week. The necessity of obtaining licenses at Washington on importations from the States is holding up some business. Deliveries from the States are getting more backward with rising prices.**

TORONTO, Ont., Jan. 29.—Another snow storm and the continued cold weather has again tied up traffic on the railways and has caused considerable inconvenience to manufacturers throughout the province. The freight congestion, more acute on account of the cold weather, is preventing the free movement of raw materials. The shortage of raw materials is also adversely affecting the industrial situation and in some cases manufacturing operations are being restricted and output consequently is curtailed.

### Steel

The situation in the iron and steel trade has not improved, in fact conditions are if anything worse due to the continuance of the severe weather. Steel plants and foundries in this district are badly in need of coke and production is being curtailed by reason of the shortage which is becoming more acute, due to the freight congestion. There is little hope of the proposed increase in production of steel materializing for some weeks as little improvement can be looked for in the transportation situation until the weather moderates for a long enough period to enable the railways to catch up with arrears in car shipments and clear the terminals. Under prevailing conditions the steel companies cannot even approach anything like maximum capacity let alone increasing it, therefore full supplies of coke are absolutely necessary before any attempt can be made to increase the steel production to the required tonnage. The situation is undoubtedly serious, but conditions are such that relief measures are difficult to put in force. The shortage of cars and severe weather [illegible] trouble, while the cold weather hampers operations at the ovens, thus reducing

A report from Ottawa states that arrangements have been made whereby a supply of ship plates and shapes can be obtained from United States for the first vessels that will be laid down under the proposed Government programme. It is understood that the first vessels will be laid down about next June. The existing shipyards will be utilized for this construction, Government ships being laid down as berths become vacant. No vessels for neutrals will hereafter be built in Canada. In view of the above arrangement it is problematical if plate rolling mills will be established in Canada in the meantime owing to the high cost and the long time that would elapse before the mills could be installed and in operation. Conditions in the steel trade across the line are not much easier in spite of the drastic measures that have been taken to relieve the fuel situation and the shortage there will affect consumers in Canada. The demands of the U.S. Government are growing heavier and are fully sufficient to keep all the the producing plants actively employed. There has been a serious falling off in the output of steel in the States the last few weeks and the continued severe weather has made matters worse. The output has probably been reduced 50 per cent. due to the weather conditions and shortage of raw material. Consumption either directly or indirectly for war purposes is absorbing practically all the steel that can be produced, leaving very little material for consumers not working on war contracts. The most serious aspect of the situation is the shortage of pig iron which is as acute as ever, due to the failure of the coke supply. Current business has been very small, but deliveries have been smaller, due to the traffic situation and the fuel shortage. Hence, it is expected that another increase in unfilled tonnages will be reported for the month of January. Earnings of the last quarter of 1917 are expected to show a decided falling off from those of the third quarter, while there is expected to be a further decrease shown in the current three-months period.

### Pig Iron

The cold weather continues to hamper furnace operations and there is no improvement in the coke situation. Cars are held up on account of the freight congestion and the movement of coke is light, intensifying the already acute shortage of fuel. As a result of this, the production of pig iron has been considerably curtailed during the last few weeks and furnaces are getting further behind on deliveries which is causing anxiety among consumers. Across the line there is little if any improvement in the situation and there is no perceptible increase in the production of iron.

### Scrap

There is no perceptible change in the old materials market, business continues quiet and prices are the same as quoted last week. Dealer's stocks of most scrap metals are low, due largely to the shortage which prevails and also because there is no inducement to carry heavy stocks on account of the unsettled outlook. Consumers are only buying hand-to-mouth owing to the prevailing impression that prices may decline. Prices of non-ferrous scrap are weak but heavy melting steel and old cast iron are firm.

### Machine Tools

Business has been rather quiet this week in machine tools in this district, and the orders that have been placed have been small. The fact that no machine tools can be imported from the States except under license is curtailing busi-

ness to some extent because it is practically impossible to obtain a license at Washington unless the machinery is required for munitions plants or shipyards. The embargo thus cuts off a certain amount of business which would in the aggregate help to swell the volume of sales. Deliveries on some tools are getting more backward which is tending to discourage buyers while high prices are also a factor in the situation. Dealers continue to complain of shipments being held up in transit.

### Supplies

Business continues brisk and prices firm. Difficulty is being experienced by dealers in obtaining some lines of machine shop supplies manufactured in the States and deliveries are uncertain. The continued high cost of practically all raw material precludes the possibility of price recessions, the tendency being upward rather than down. There are no price changes of importance to note this week.

### Metals

There have been no important developments in the metal markets except that President Wilson has approved the recommendation of the War Industries Board that the price of copper shall be continued until June 1, although this caused some disappointment in the trade, no change has come over the copper situation. What little tin there was in the States has been commandeered for the use of the Emergency Fleet Corporation, causing some concern by the trade. The lead market remains firm but spelter, antimony and aluminum are quiet and unchanged.

**Copper.**—The price of copper fixed at 23½c last September by the War Industry Board will be continued in effect until June 1st. The recommendation of the Board has been approved by President Wilson. The government's decision has caused some disappointment in the market as it has been predicted in many quarters that the price would have been raised to 25c to stimulate production as a number of mining companies are reported to be unwilling to undertake extensive additions to their work unless a higher price was paid for copper. The supply of the metal is not enough for full needs at the present time, but some industries have curtailed their buying and thus no serious shortage has been seen. It is said in the copper industry, however, that if there should be any revival of general activity in the lines which use the most copper a decided shortage in spot supplies would be quickly seen. Local copper prices are unchanged, lake and electrolytic being quoted at 31c and casting at 30c per pound.

**Tin.**—The tin situation in New York is more acute and trading has practically ceased on account of the uncertainty in regard to future developments in the market. The U.S. Government has commandeered all tin in New York warehouses which has created some concern in the trade although little disturbance is expected as all the tin had been sold and was being held for consumers' account. Local situation is unchanged and quotations are nominal at 80c per pound.

**Spelter.**—The market continues dull and little interest is being shown in spelter. In the primary market efforts have been made to have the U.S. Government agree to an established price of 10c but so far nothing has been done. Local price 10½ per pound.

**Lead.**—The market remains firm and quotations unchanged. The lead situation is unchanged and so far as supplies are concerned is likely to remain so. The indications are that prices also will not undergo much change, because the leading producers are understood to be opposed to advancing prices at the present time. Local price 9c per pound.

**Antimony.**—The market is quiet again with an easier tendency and the price is unchanged at 17c per pound.

**Aluminum.**—The market is quiet and easier with no change in the situation. Local price 60c per pound.

### CANADIAN GOVERNMENT PURCHASING COMMISSION

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

## New York

NEW YORK, Jan. 26.—Manufacturers who have received recent contracts for war munitions from the United States Government have placed supplementary contracts for shop equipment and other industrial concerns that expect to close for shells and shell accessories are tentatively in the market for machine tools. The Emergency Fleet Corporation has also released additional orders for cargo boats and the shipyards are buying machinery as a result.

### Recent Contracts

For the Government nitrate plant at Mussel Shoals, Ala., the Air Nitrates Co. of New York has purchased 15 electric and transfer cranes. The Neptune Meter Co. of Long Island City, which has a fuse contract from the Government, has placed orders for tools. The Worthington Pump & Machinery Corporation has bought additional machinery for its Hazleton, Pa., plant, and the Bartlett-Hayward Co., Baltimore, which is making shells for the Government, has placed supplementary orders for machine tools. The John Thompson Press Co., New York, which expects a Government contract for projectiles, is testing the market for tools. The Zenith Carbureter Co., Detroit, has bought 20 machines in the Cleveland market for munitions work.

### Shipbuilding Prospects

Although shipyards have been sadly handicapped by railroad embargoes, labor difficulties, and unfavorable weather, they have continued to make preparations for greater activity in the next few weeks. The Federal Shipbuilding Co. has purchased 11 travelling cranes for its Newark shops from the Milwaukee Crane & Manufacturing Co., and has also purchased $100,000 worth of heavy tools taken from the plant of the Stewart-Warner Speedometer Co., Long Island City, which plant was recently taken over by the Government for the manufacture of gas masks. Only a few of the tools were commandeered by the Government, the other machinery being offered in the open market through Carpenter & Woodward. It is claimed that the equipment is worth about $500,000 at present market prices. The Atlantic Corporation, Portsmouth, New Hampshire, which is to build ten steel ships for the Emergency Fleet Corporation, is enlarging its plant to execute the contract, and is now buying equipment which will cost in the neighborhood of $1,000,000.

On the Pacific coast the machinery trade is receiving supplementary orders from shipyards. The Moore Shipbuilding Co., which has a contract to build 16 more steel freight boats for the Government, is building two more shipways and buying necessary plant equipment. The Union Iron Works, San Francisco, has been authorized by the Shipping Board to build four additional slips at its Alameda plant to construct more ships for the Fleet Corporation.

### Export Handicapped

Export trade in machinery, outside of Government purchases for France, is almost entirely suspended. The latest Government inquiry is for 25 chain hoists for the American Ordnance Base Depot in France. New York agents who are buying for the Italian Government are anxious to place additional contracts for machine tools, but can obtain no promises for definite shipment, as the manufacturers and dealers are already overwhelmed with domestic orders mainly for the Government, either directly or indirectly. Some war plants in Italy cannot be completed because neither corrugated steel sheets nor machinery can be obtained in this country. Orders for machine tools placed over a year ago for Italian plants have not been filled; some of the tools have been commandeered by the United States Government. Over 100 similar cases are reported. It is an interesting fact that one large Italian gun shop has been entirely built from American steel and equipped with machinery from the United States. The equipment alone has cost $6,000,000. It is expected that some of the manufacturers in Italy now engaged in producing war equipment will make an effort to manufacture agricultural implements after peace has been declared.

## Washington

WASHINGTON, Jan. 26.—While par- [illegible] has been [illegible] in Washington during the past week. Commercial and industrial men of the United States have been in a quandary as to the future status of their business.

Dr. Garfield's fuel order closing down all factories not engaged in war work has resulted in serious cramping of industries and on top of this has come an order from Director-General of Railroads McAdoo placing an embargo on all freight, except coal and food, on the two principal carriers east of Pittsburgh. According to reports received here the fuel order was very generally obeyed, not without serious protest, however. There have been intimations that it might be found possible to abrogate the order before April 1, as at first planned, but continued severe weather discounts this hope. Many factories have taken opportunity of the enforced shut down to make repairs.

### Munitions Director Wanted

With President Wilson fighting bitterly Congress is still waging a war to secure a Director of Munitions. Business men throughout the entire nation are supporting this move and maintain that greater centralization of power would result in better co-ordination of the American industries making munitions of war. Secretary of War Baker, a strong opponent of the Director of Munitions plan has already taken a step in that direction by the appointment of Edward R. Stettinius as "surveyor general" of all army purchases. Stettinius has been a member of the firm of J. P. Morgan and for several months previous to the entrance of the United States into the war was engaged as the chief purchasing agent of the Allies in the United States. His name had been mentioned as a possible man to fill the cabinet office of the proposed Director of Munitions.

### Shipping Board Troubles

Controversy over the shipbuilding possibilities of the United States goes merrily on. Advocates of a Director of Munitions maintain that such an officer would have power over shipbuilding and would be so able to centralize the power that the tonnage capacity of the United States might be increased by at least 1,000,000 tons a year. The investigation into the Shipping Board, being conducted by the Senate, has brought about a wholesale reorganization in the department of design of the Shipping Board. Because certain testimony given before the Senate committee tended to show that he had not been entirely in full co-operation with [illegible] resigned and in justification of their chief eight of the subordinate designers resigned at the same time. The testimony [illegible] ...es which had no shipyards but were and testified that the lack of labor and proper living conditions has held the operations of the United States in ship construction down to seventy per cent. of their capacity.

### Coal Zones Include Canada

Dr. Harry A. Garfield, Federal Fuel Administrator, has in view a new plan for the distribution of coal which will necessarily affect Canada. Dr. Garfield plans to divide the country into twenty zones. Each zone must draw its coal supply from within the zone. Statisticians are now at work in an attempt to fix zone lines in order that there may be a balance between the supply and the demand within the zones. Details of the plan have not been finally completed, but it is understood that Canada will be included in one of the zones. According to the best information Canada will be placed in a zone which will include Ohio, Indiana and a part of Pennsylvania. This will mean that Canada's coal supply must come from this zone and will necessitate the changing of contracts held by some Canadian manufacturers for coal in other zones. Dr. Garfield has before him a plan which will allow present contracts to be fulfilled, but no future contracts can be made with dealers outside the zone. It is believed that Dr. Garfield will consider Canada as a part of the United States rather than rating it as a country to which coal is exported, because the export coal will be ordered drawn from those coal fields nearest the Atlantic ports, whereas he favors Canada's coal supply coming from fields near the lake ports.

### Fisheries Adjustment Begins

The Canadian Fisheries Board here adjusting the question of rights of fisheries in the United States and Canada will begin hearings in Boston on Jan. 31. Later they will go to the Pacific Coast for a series of hearings.

Secretary of the Interior Lane has announced that the Nenana coal lands in Alaska will be opened for leases within a few weeks.

The Navy Department is calling for bids on valves, air, gate, steam, water, high and low pressure, for delivery at the Puget Sound Navy Yard. Bidders desiring to offer bids should apply to the Navy Purchasing Bureau, Navy Department, Washington, D.C., asking for schedule 1660. Applications may also be made for the schedules, which contain full details, to the nearest navy yards. Bids are also being asked for miscellaneous hardware, such as chains, locks, wire cloth and so forth. These specifications are described in schedules 1660 and 1661, which may be procured through the same sources.

The iron and steel market in the United States has been greatly upset by the Fuel Administrator's closing order according to reports received here. Estimates placed before government bureaus indicate a shortage of approximately twenty-five per cent. due to the closing order and a general shortage in pig iron from blast furnaces.

## Pittsburgh

PITTSBURGH, Pa., Jan. 26.—During the five-day period ending midnight Tuesday, Jan. 22, covered by Fuel Administrator Garfield's plant closing order, the blast furnaces operated as far as they were able to operate. The Bessemer steel-making departments were all closed, except that two or three resumed Monday morning by reason of the tin plate mills having been given an exemption late Saturday night. The open-hearth steel departments generally were closed, but 20 or 25 per cent. of the normal tonnage was turned out in connection with exempted finished products. Finishing departments generally were closed, the exempted departments representing only a very small percentage of the total capacity. The exemptions as a rule were not received until after departments had closed, some of them not coming until Saturday night, and resumption was difficult. Some were even received Monday and Tuesday, and, therefore, proved of significance only as to the nine following Mondays on which plants generally are to be closed.

While the plant closing order caused a great deal of comment and considerable excitement, it was to the steel industry only an incident. Steel mills are accustomed to sudden closings for one thing, while shipping conditions have been so extremely bad that the steel industry was disposed simply to hope for the best in connection with this drastic order. While there was much criticism of the order in many circles at the outset, there was practically none at any time in the steel industry. The criticism elsewhere has largely died down, as the necessity for the order has come to be appreciated.

### Traffic Conditions

In the first week of the month the majority of railroads serving the Pittsburgh and valley mills placed embargoes against the receipt of freight for most points, with a few exceptions. Shipments were accordingly greatly curtailed. A fortnight ago hopes were entertained that these embargoes would be removed by the end of last week. Instead of that the plant closing order announced Thursday was tacit notice that nothing of the sort could be expected. Wednesday of this week Director-General of Railroads McAdoo, upon recommendation of Mr. A. H. Smith, president of the New York Central and regional director of the Eastern roads, instructed Mr. Smith to order embargoes against the receipt of all freight, except perishables, fuel and war material, on the Pennsylvania lines east of Pittsburg, the Baltimore and Ohio, east of the Ohio River, and the Philadelphia and Reading. This order served to extend somewhat the scope of the previous embargoes, and it is taken to indicate that the railroads will grant practically no permits to ship through the embargo. The roads had not been issuing many permits, however.

While the curtailment in the shipment

of coke has increased progressively, until blast furnaces in the central west in the past week or two have been operating at only 50 to 70 per cent. of capacity, the conditions as to shipment of finished steel have become such that the greatest restriction is in that quarter. The mills can ship less finished steel than they are able to produce even with the restricted supply of pig iron. On an average shipments of Pittsburgh and valley mills in the past two or three weeks have represented only about 50 per cent. of capacity. The production has been a trifle more than that, but not much more, as so much material has accumulated in mill warehouses and yards that various departments have already been forced to curtail production.

### Coke and Blast Furnaces

Shipments of Connellsville coke in the week ended January 19 are reported by the Connellsville "Courier" at 247,487 net tons, against 290,718 tons the preceding week, an average of about 350,000 tons a week in 1917, and an average of 421,000 tons in 1916. The blast furnaces could have stood a slight decrease in shipments, as new by-product coking capacity has been put in operation, but not a great deal. It is positively asserted that there is an ample supply of labor in the coke region, and that the curtailment in shipments is due entirely to car shortage.

Strenuous efforts have been made of late to improve conditions on the railroads, but on account of extremely adverse weather conditions results do not show as yet. Shippers are now doing their part in eliminating the cross movements, about which there was so much complaint recently, as they resulted in much coke being hauled a greater distance than necessary, incidentally congesting some yards. Several important interchanges have been effected, these being in essence an exchange of customers between coke works, and matters are well in hand in this respect.

### Weather Dominant Element

While the various efforts that are being made to relieve traffic conditions are interesting, and more or less important in their way, practical men in the coke, blast furnace and steel industries are all thinking much more of the weather than of these human efforts. They insist that the weather is the dominant element, that conditions would not have become nearly as bad if the winter had not been an unprecedentedly hard one, and that there is going to be important and rapid improvement in traffic conditions as soon as the weather becomes half favorable. It is a matter of the progress of the calendar, however. The weather has grown worse to-day, colder and with more snow, and with predictions by the Weather Bureau of another cold wave. In a few weeks, however, it is reasonably certain there will be fairly mild weather, such as will permit the railroads to get into working order again. The measures being taken are relieving congestion to an extent, and they prevent further congestions arising, so that when locomotives become able really to pull trains there will be fairly clear track for them.

### Market Prospects

There is, of course, no market at present. No one is thinking of buying or selling pig iron or steel products, except that there is a little activity in second half foundry iron at prices subject to revision to any new Government schedule that may be put out after March 31. Buyers are specifying rather slowly on regular contracts for steel products, and are not particularly urgent about shipment of material already specified, even though their receipts have of late been greatly diminished. The future of the market hinges upon the relation between the effect the traffic blockade has had upon production and the effect it has had upon consumption. If favorable weather results in production of steel at or near capacity and consumptive demand does not increase steel will be a drug upon the market. If the consumptive demand increases proportionately with the production there will be a firm and active market. There are many who believe this will occur, but there are some who think that eventually the increase in production will be greater than the increase in consumptive demand.

Government orders are being placed substantially at the same rate as formerly, there being large tonnages let from week to week, but except in a few instances the details are withheld.

## MIDLAND SHIPBUILDING CO.

THE Midland Shipbuilding Co. of Midland, Ont., although devoting its energies principally to repair work, will shortly lay the keel of a steel freighter which will be 261 feet long, 43 ft. 6 inches beam, and 23 feet deep. The company is repairing the C.P.R. steamer Athabasca which was damaged late in the season by ice. Twenty new plates are being replaced in her bow.

The forward end of the steamer Mariska is undergoing extensive alterations, a new forecastle and steel deckhouse being built upon her and equipped.

A new steel deck-house is also being built forward on the steamer Glenlyon of the Great Lakes Transportation Co., including captain's and mate's accommodation. A new steel deck house [illegible] and various minor repairs are being made in the hull.

All the big beams and stanchions are being removed from the Western Star, of the Great Lakes Line, which is being reconstructed to the Herriman type of lake cargo steamers. The wood-work in the after cabin is being rebuilt and the engines and boilers overhauled.

The W. C. Franz, of the Algoma Steamship Co., will appear in the spring as a Herriman type of lake carrying steamer.

The boilers and engines of several other ships in the harbor are being overhauled. Though reconstruction work is taking up a great part of the company's time, the management is looking forward to commencing operations on the new ships as soon as the steel arrives, and it is expected daily.

## TENDERS WANTED

TENDER forms and specifications have been received from D. H. Ross, Canadian Trade Commissioner, Melbourne, for equipment required by the Department of the Navy, Melbourne, and the Postmaster General's Department, Brisbane, Queensland. These tender forms are open to the inspection of Canadian manufacturers at the Department of Trade and Commerce, Ottawa. (Refer File No. 1729 O.) Particulars of the requirements are briefly outlined thus: The tender addressed to the Director of Navy Contracts, Navy Office, Melbourne, is as follows:—Supply and delivery of one motor driven hydraulic pump for Garden Island, Sydney, N.S.W. Date of closing April 5. Tenders addressed to the Deputy Postmaster General, Brisbane, Queensland, are as follows: Schedule. No. 432. Fifteen miles, 550 yards silk and cotton insulated switchboard cable, as specified; 990 yards paper-insulated, rubber covered cable, as specified; 8,880 yards lead-covered, paper-insulated telegraph cable, as specified. Date closing Feb. 27.

## TRADE ENQUIRIES

THE following enquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be had on application.

34. **Electrical supplies.**—A firm in Barbados handling electrical supplies would be glad to communicate with Canadian manufacturers of such supplies.

37. **Raw potash feldspar.**—A Midlands, England, company asks to be placed in communication with Canadian producers of raw potash feldspar, favourably situated for export to the United Kingdom.

38. **Vulcanizing machinery.**—A manufacturing firm in St. John's, Newfoundland, asks to be put into communication with Canadian exporters of machinery for vulcanizing automobile tires.

39. **Marbleized tin.**—Canadian manufacturers of marbleized tin in size 20 by 40 inches are asked to communicate with a Newfoundland inquirer.

## MAIMED SOLDIERS TAKE 94 DIFFERENT COURSES

THE elasticity of the work offered by the vocational training branch of the Military Hospitals Commission in its efforts to meet the needs of every soldier who returns to Canada so disabled as to require a new vocation adapted to his altered condition can be measured in some degree by the figures lately compiled showing that 94 different courses are now being taken.

The work is largely individual although in some courses greatly in demand

classes are conducted. These include motor mechanics, tool-making, draughting, book keeping and commercial work, shoe-making, agriculture, etc., and sometimes the enrolment in certain classes is over a score.

The courses are listed under five heads, agricultural, trades, professional, mechanical and miscellaneous. Some are being taken in universities, some in factories, some on the land, some in the schools specially established by the M.H.C. All are roads to independence and a new livelihood.

### Many Moulds

The vocational experts are not trying to turn maimed men into a few set moulds but to afford every man the particular training required to best utilize his previous experience and secure his future. This aim is accountable for the breach between a course in saxaphone instruction given to a Montreal piano teacher whose shoulder was shattered in France and boiler-making for a day-laborer with mechanical ingenuity who lost a leg.

### Valuable Abilities Developed

Some men must receive the necessary instruction in a university. If this is so, the vocational experts arrange for them to have the course. Other men will regain independence by learning in some factory a trade related to their previous occupation. Still others will go on the land. Wherever they can be most efficiently and economically trained the course is given with the realization that the man's most valuable abilities are to be developed not only for his welfare but for Canada's.

## SOUTH AFRICA'S IRON AND STEEL INDUSTRY

IT is quite conceivable that, before many years have elapsed, Pretoria will develop into a great industrial centre for the production of iron and steel, and become a "Sheffield" in miniature. It has, of course, always been known that abundant deposits of iron ore of a quality which makes it extremely valuable from the commercial point of view exist in the Pretoria district; but it is only recently that the Corporation has taken the definite step of leasing to a local company a small portion of the ore-bearing area.

The company in question has been promoted by Mr. C. F. Delfos, of the well-known engineering firm of Delfos, Ltd., Johannesburg and Pretoria, who are, of course experts in this branch [illegible] the ore, as also that found near Barkly West, in the Cape Province, will shortly begin operations. Inquiries have, however, been received from other quarters and from other persons who desire to take a much larger share in the mining of iron in this region; but the [illegible] Ordinance of

(Continued on page 122)

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE—Valparaiso, British Consul General.

COLOMBIA—Bogota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE Havre, British Consul General. Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL Lisbon, British Consul.

RUSSIA Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Bahia, British Consul. Rio de Janeira, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

### CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

### CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum, Grubbegd No. 4 Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

### CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

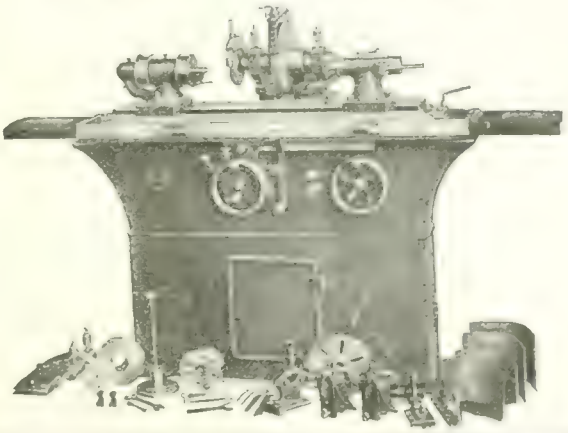
Use it for grinding straight and taper cylindrical parts, chuck and face plate work, etc. Fast, efficient, economical, sturdy. 9" x 26"—wheel 10" x 1".

## OTT GRINDER CO.

**INDIANAPOLIS**

Canadian Representatives
Geo. F. Foss Machinery & Supply Co., Montreal



# Special Purpose Tools

## For Shell Making

For nearly three years we have been making shells in our own factory. To turn these out economically we have designed many special purpose tools. We have found that these will do the work for which they were designed, as well as the more expensive general purpose tools, that they are easily operated by inexperienced workmen, and are not so apt to get out of order as the more complicated tools. We are now offering them for sale to other shell factories.

Boring Lathes
Base Boring Lathes
Waving Lathes
Band Turning Lathes
Hydraulic Band Presses
Shell Grinding Machines
Shell Cleaning Machines
Undercutting Machines
Finish Tapping Machines
Inside Profiling Machines
Nicking Machines
Centering Machines

We can supply any of the above complete, ready for use, at about half the cost of ordinary tools for the same purpose, or we can furnish you with a complete set of castings ready for you to machine and set up.

## MARSH & HENTHORN, Ltd.

**BELLEVILLE** **ONTARIO**

# INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## ENGINEERING

**Redcliffe, Alta.**—The Alberta Rolling Mills are building an extension to their plant here.

**Hamilton, Ont.**—The Canada Steel Goods Co. will build a factory addition to cost $150,000.

**Tillsonburg Ont.**—The Maple Leaf Harvest Tool Co. contemplate building an extension to their factory.

**Vancouver, B.C.**—The Canadian Metal & Equipment Co. propose establishing a smelter at False Creek.

**Merritton, Ont.**—The Riordon Pulp & Paper Co. will instal power equipment at the mill here. Head office, Montreal.

**Nelson, B.C.**—The Waneta Power Co. is engaged in the development of a large water power on the Pend d'Oreille River, south of Nelson.

**Toronto, Ont.**—A building permit has been issued to Reid & Brown for the construction of a structural steel shop at 63 Eplanade ave. east, to cost $4,000.

**Welland, Ont.**—The Provincial Natural Gas Co. at the week-end struck a large gas well which will go a long way to relieve the gas shortage in Welland and other municipalities. This well is said to have a flow of two million. Gas was struck at a depth of 3,380 feet, so the well must be counted one of the deepest in this section.

**Gowganda, Ont.**—The South Bay Power Co. will install a 500 h.p. electric unit and proceed with the diversion of the East Montreal River. The company fully expects to carry out its original plan, that is, to install a 1,500 electric horse-power plant at Hangingstone Falls, Gowganda Lake, for the purpose of supplying electric power to the mines at Gowganda. First, to install a 500-horse-power unit, part of the electric energy from same to be used to drive a tunnel to divert the East branch of the Montreal River into Hangingstone Lake, which will give water enough to develop an additional 1,000 horse-power. The Reeves-Dobie Mining Co. is assisting in the financing of the company for the purpose of securing electric power to operate their mine.

**Sudbury, Ont.**—The proposal of the British-America Nickel Corporation to [illegible] power from a development plant on the French River has been definitely abandoned, owing to the prohibitive cost involved, according to a report current here. In consequence of this it is thought probable that the company will establish a refining plant [illegible] the war all kinds of material have ad-

that power could not be developed on the French River under $40 or $50 per horse-power. The Hydro Commission, therefore, advised against the French River proposal and advocated the establishment of a nickel refinery in the Ottawa Valley. In the meantime, the British-America Nickel Corporation will likely install a steam plant at the Murray Mine to supply some of the power needed.

## ELECTRICAL

**Windsor, Ont.**—It is likely that before long the Hydro Commission will purchase the Essex County Light and Power Co.'s plant and business. The plant is at present owned by the Detroit Edison Co. of which Alex Dow is president. This company supplies power to Windsor, Walkerville, Sandwich and Essex. Negotiations for the purchase have been proceeding for some months, but the deal has not been completed yet. The price will be likely around $200,000.

**Guelph, Ont.**—A movement is on foot in this city to develop the unused power on the Speed River in the neighborhood of the Ontario Military Hospital. Several farmers have become interested in the scheme, with the hope that they may be able to secure power for use on their farms. It is understood that R. H. Clemens, district representative, is taking up the matter with the Hydro-Electric Power Commission, and an engineer will make an inspection soon.

## GENERAL

**Halifax, N.S.**—Hillis & Sons, are considering rebuilding their factory.

**Oakville, Ont.**—The plant of the Ontario Brick Co. has been sold by the liquidators, Ward, Price Ltd. The purchaser was F. W. Palfield, of Montreal, who represents Eastern interests, and the price paid was $250,000.

## TENDERS

**Brantford, Ont.**—Tenders will be received until Thursday, Feb. 7th, 1918, for one 40 h.p. vertical induction motor, switchboard, and accessories, with installation at the Sewage Pumping Station, Brantford, Ont. Specifications may be obtained on application to the city engineer, T. Harry Jones.

**Ottawa, Ont.**—Tenders will be received until Feb. 5, 1918, for the elevators and hoist equipment required in the re-construction of the Parliament Buildings. All tenders to be based on the execution, erection and completion, together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for elevators and hoist equipment. The work of this contract shall be proceeded with immediately upon the signing of the same and continued as directed, in such a manner as to insure the completion thereof by Dec. 1, 1918. Plans and specifications, and any other information required can be obtained at the office of the General Contractor, P. Lyall & Sons Construction Co., Ottawa.

**Ottawa, Ont.**—Tenders will be received until Feb. 5, 1918, for rolled steel casements and bronze covered frames and sash for the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for (a) rolled steel casements; (b) bronze covered frames and sash. Separate tenders to be submitted for "a" and "b." The work included under this contract shall be commenced immediately on the signing of the same, or at such time as may be directed, and be carried out in such a manner as to insure the completion thereof by Sept. 30, 1918. Plans and specifications, and any other information required can be obtained at the office of the General Contractor, P. Lyall & Sons Construction Co., Ottawa.

## MUNICIPAL

**Mitchell, Ont.**—The Town Council are considering the advisability of installing a gasoline engine and pump.

**Newboro, Ont.**—A by-law has been passed giving the contract to J. P. Tett & Bros., for supplying electric light to the village. Power will come from Bedford Mills.

**Penticton, B.C.**—The City Council contemplate an expenditure of $20,000 for the construction of certain works in connection with the domestic water system and $35,000 for works in connection with the irrigation system.

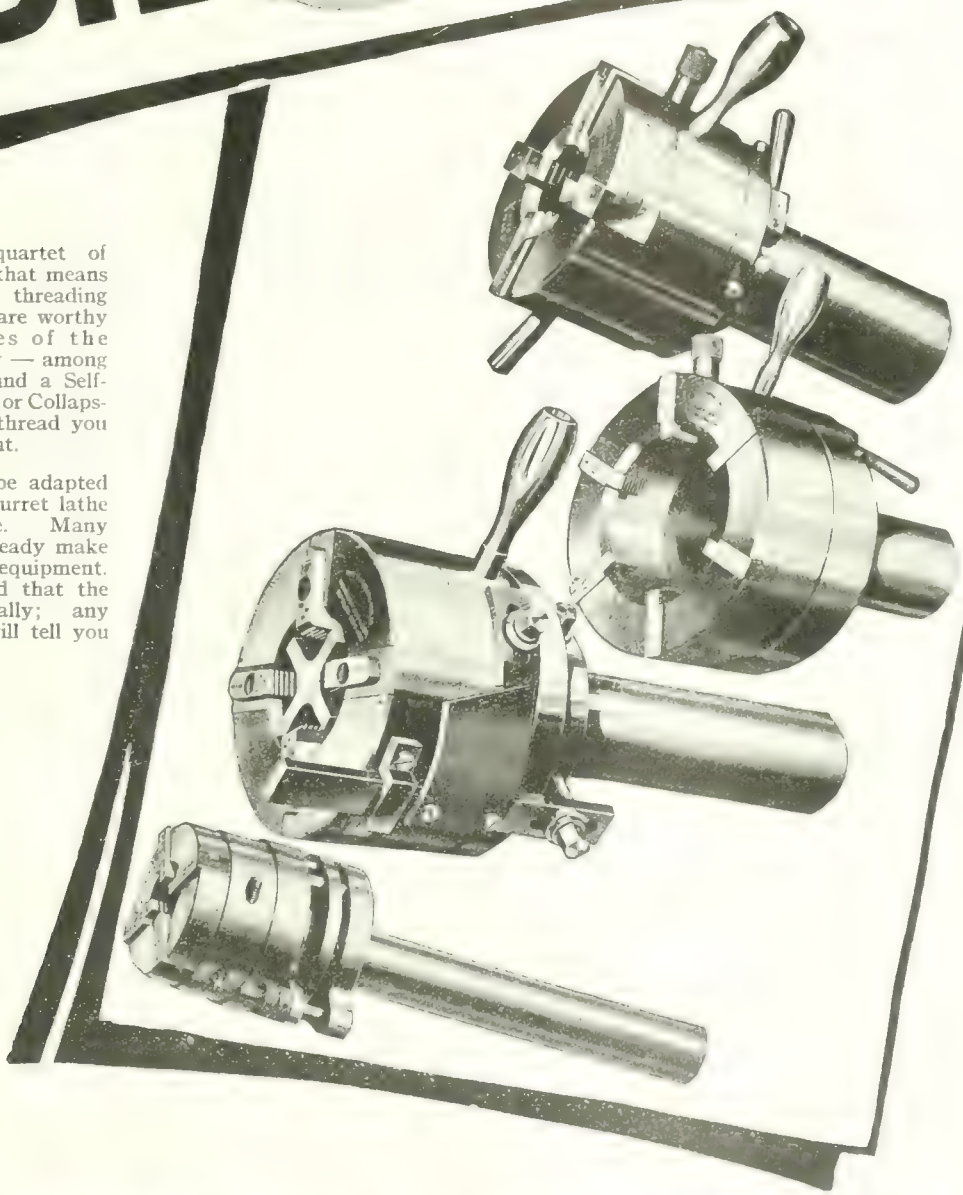
**Vancouver, B.C.**—The following by-laws have been defeated by the ratepayers. A grant of $120,000 to the Y.M.C.A. in order to assist in completion of building; $26,500 for constructing and equipping a high school; $53,500 for heating and ventilating and general school purposes and $66,000 for constructing and equipping additions to school buildings.

## PERSONAL

**James H. Munro**, founder of the Munro Wireworks, Winnipeg, died on Jan. 17, following an attack of apoplexy.

**Henry J. Fuller**, president of the Canadian Fairbanks-Morse Co., Montreal and Toronto, has been elected a director of the Liberty National Bank of New York City.

# GEOMETRIC DIE-HEADS



HERE'S a quartet of die heads that means death to threading trouble. They are worthy representatives of the Geometric family — among which can be found a Self-Opening Die Head or Collapsing Tap for any thread you could possibly want.

These tools can be adapted to any make of turret lathe or screw machine. Many manufacturers already make them standard equipment. We are convinced that the rest will, eventually; any Geometric user will tell you **why**.

## THE GEOMETRIC TOOL COMPANY

**NEW HAVEN** **CONNECTICUT**

**Canadian Agents: Williams & Wilson, Limited, Montreal; The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg and St. John, N.B.**

Edward G. Mack, managing director of the Cosmos Hosiery Co. of Cowansville, Ltd., Toronto, has been elected to the executive council of the Toronto Board of Trade for the ensuing year.

Alderman W. S. Weldon of Montreal, has been appointed Collector of Customs of the Port of Montreal. He was at one time president of the Montreal Amateur Athletic Association.

Capt. James Lanaway, a former resident of Woodstock, Ont., died in Seattle on Jan. 27, aged 58. For many years prior to going west seven years ago he was a captain on the Great Lakes.

Flight Lieut. Ralph Gordon Hall, of the Royal Flying Corps, was accidentally killed while flying at Birmingham, England, on Jan. 22. His father is Thomas Hall, president of the Hall Engineering Works, Montreal.

W. F. Tye, of Montreal, president of the Sterling Coal Co., Toronto, and former chief engineer of the C.P.R., has been named a member of the Commission of conservation to succeed the late Sir Sanford Fleming.

Lloyd Harris, president of the Russell Motor Co., is being mentioned as likely to be appointed Canadian representative at Washington. Mr. Harris is already in the American capital as the agent of the Imperial Munitions Board.

**Sir John Wolfe, Barry,** widely known engineer, officer of numerous engineering and allied societies, member of the army railway council and consulting engineer to many railway and public works corporations, died in London on Jan. 22. He was born in 1836.

Lieut. S. S. Smith, formerly sales and credit manager for the Lake Winnipeg Shipping Co., Winnipeg, Man., who was reported missing early in June, is now officially presumed to have been killed in action. Lieut. Smith went overseas with a Winnipeg battalion in Oct., 1915.

F. C. Winterburn, chief engineer of the steamer Quadra, died at St. Paul's Hospital, Vancouver, B.C., on Jan. 12. He was 57 years of age and had done duty in England as inspector of munitions for over two years, having heard the call of his country in 1915 while working at the Yarrow yard at Esquimalt. He returned to British Columbia six months ago and shipped as chief of the Quadra on the ore trade between Britannia Beach and Tacoma.

Lieut. Harold H. Vroom has invented a gyroscope control for the Vroom hydroplane which has been accepted by the British Admiralty. Lieut. Harold H. Vroom is a son of Ald. E. G. Vroom, of [illegible], Montreal, and a native of St. Stephen, N.B. He was educated at [illegible], being graduated in 1910 with the degree of Bachelor of Science. In May 1916, he enlisted as [illegible] in the motor patrol service [illegible] in the work of [illegible] of 1917.

Albert George Hill, late manager of Babcock & Wilcox, Ltd., Toronto office, Imperial Munitions Board, with headquarters in Toronto. Mr. Hill will have charge of production of marine engines and boilers in the Toronto district. Mr. Hill was with Babcock & Wilcox, Ltd., in charge of the Toronto office for five years, having previously been with the Drummond, McCall & Co., Toronto office, in the engineering department. He was two years with this concern as sales engineer in Toronto district and Western Canada. Prior to coming to Canada Mr. Hill was for some years with Alley & MacLellan, Ltd., of Glasgow, in the marine and high-speed engine department, and previously with Deacon & Foster, consulting engineers, of Birmingham, England.

**Henry Hague Vaughan,** formerly of the C.P.R. and now vice-president and general manager of the Dominion Bridge Co., has been elected president of the Canadian Society of Civil Engineers now known as the Engineering Institute of Canada. Mr. Vaughan was born in England in 1868 and came to the United States in 1891. He became mechanical engineer of the P. & R. R. and later superintendent of motive power in the L.S. & M.S.R. Mr. Vaughan came to Canada in 1904 as superintendent of motive power of C.P.R. lines, east and in 1905 became assistant to the vice-president of the C.P.R. During this time he had charge of the Angus Shops, and the car and locomotive equipment service of the C.P.R. In 1916, Mr. Vaughan left the C.P.R. to become president of the Montreal Ammunition Co., and in 1916 he organized the Dominion Copper Products Co., of which he became president and general manager. These companies were later absorbed by the Dominion Bridge Co., whose staff Mr. Vaughan joined in 1916 as vice-president and general manager.

## TRADE GOSSIP

**Lindsay, Ont.**—The Town Council may decide to take over the Fitzsimmons auto body factory.

**The International Malleable Iron Co.,** of Guelph, Ont., has increased its capital stock from $250,000 to $500,000.

**The Elliott Co.,** manufacturers of power accessories, have disposed of their office building in Pittsburg, Pa., and have taken a spacious suite of offices in the Frick Building in that city.

**The Liberty Manufacturing Co.,** manufacturers of boiler tube cleaners, have removed their offices from Susquehanna street to the Frick Building, Pittsburg, Pa.

**Erratum.**—In the review of the Motor Marine and Aircraft Redbook in the Dec. 6 issue of CANADIAN MACHINERY, an error was made in the price of this publication which should have been 5/6 ($2.10) and not 5/6 ($1.40) as stated.

**U.S. Army Will Use Metric System.**—Adoption of the metric system of measurement for artillery and machine guns and maps for the American overseas forces was announced recently by the War Department at Washington.

**Airplane Engine a Success.**—The first of one thousand aeroplane engines being built in Toronto was satisfactorily tested recently. The engines are being constructed at the plant operated by the Imperial Munitions Board.

**Fort William, Ont.**—The Canadian Car and Foundry Co. plant is about completed. Early next month the work of making cars will be commenced, when 1,100 men will be employed, increasing to 1,500 and 1,700 as the capacity of output is reached.

**Canada and U.S. Pool Steel Supplies.** Arrangements are in progress between the Canadian and United States Governments for pooling supplies of steel for shipbuilding purposes in connection with the Canadian policy of shipbuilding under Government operation or control of shipyards.

**Toronto Board of Trade Council.**—The following were elected members of the Council at a meeting of the Toronto Board of Trade in Jan. 24. J. D. Allan, Hugh Blain, J. L. Campbell, Col. W. F. Cockshutt, M.P.; B. B. Cronyn, R. Eaton, Charles McD. Hay, Edward Hay, Arthur Hewitt, A. O. Hogg, John G. Kent, Edward G. Mack, J. F. Michie, A. R. Reid and H. G. Stanton.

**Ottawa, Ont.**—The City Council has made application to the Ontario Municipal Railway Board for a hearing in connection with a by-law to raise by way of debentures $250,000 for the purpose of establishing a municipal fuel depot. The Board instructed the applicant city to first pass the by-law as proposed, when a date for the desired hearing will be fixed.

**Cannot Build Ships for Neutrals.**—It has been decided, with a view to meeting special British requirements, that no further orders must be taken in Canada for new vessels other than of Canadian or British register; at present a number of new ships are being completed in Canada on Norwegian order. As soon as the ships under construction are completed other vessels will be laid down under the Government programme.

**Shawinigan Falls, Que.**—The Canadian Aloxite Co. are building a factory here for making aloxite and carborundum. The buildings cover a wide area and are of steel construction. The aloxite mixing building is 60 x 162 ft.; the carborundum building, 60 x 113 feet; the aloxite building, 59 x 162 feet, and the main building, comprising offices, machine shop, boiler room, etc., 64 x 160 feet. The Church, Ross Co., of Montreal, are the contractors.

**Oxygen to Run Power Engine.**—Production of motive power and light from the oxygen of the air at practically no cost except that of the original installation of the plant has been accomplished by Patrick K. Gallagher, of Nelson, B.C. For some years he has been working on his invention, and it has now reached the stage where he is developing an internal combustion engine, in

which oxygen will take the place of gasoline, gas or oil.

**International Engineering Works Control Changes.**—A majority of the stock of the International Engineering Works, Amherst, N.S., has passed into the hands of a syndicate composed of several leading Canadian business men and manufacturers. The company will be reorganized and placed on a more satisfactory financial basis. A circular recently issued states that the company sustained a loss with its munitions contracts during first nine months of 1917.

**Copper Price Extended.**—On Jan. 23 President Wilson approved the recommendation of the War Industries Board that the maximum price for copper fixed upon its recommendation by the President and announced September 21, 1917, be continued in effect upon the same conditions until June 1, 1918. The maximum price under this action will be 23½ cents per pound f.o.b. New York, subject to revision after June 1, 1918, upon these conditions.

**Special License Needed for Hardware Exports.**—The Deputy Minister of Trade and Commerce, Ottawa, has received the following cablegram from the Canadian High Commissioner in London:—"The Department of Import Restrictions advises the revocation of general licenses in respect to hardware, taking effect on February 1st. From that date the special licenses will be issued on a rational basis. Goods covered by general licenses will be admitted on proof of despatch to consignees on or before January 31st."

**No Rate Increase Till After March 1.**—The increased freight and passenger railway rates raised by the Dominion Railway Board in its judgment of December 26, 1917, will not become effective until some time in March. The increases, with the exception of the rates on wheat, deferred by a special judgment of the board until June 1, were to have become effective on February 1. The postponement of the date until some time in March is the result of the protests made to the Cabinet Council by the Western Provincial Governments and public bodies with whom were associated the organized farmers and some of the business interests of Ontario.

**Saskatoon, Sask.**—The contract has been let for the installation of the refrigeration machinery for the public co-operative cold storage system in Saskatoon being operated by the Saskatchewan Co-operative Creameries to the Canadian Ice Machine Co., of Toronto and Winnipeg. The total cost of the building and machinery will be about $125,000; of this amount the machinery alone will cost $60,000. The building has a total cold storage space of 206,000 cub feet. The machinery will comprise two 35-ton York compressors and condensers, electric motors, etc., equal to the cooling power of 70 tons of melted ice every 24 hours.

**U. S. Concerns Would Start Steel Plants in Canada.**—It is reported in Ottawa that the Dominion Government has received tentative offers from large American companies desiring to engage in the

manufacture of steel for Canadian ships. These companies, however, required encouragement in the way of bonuses and concessions before taking up the manufacture of steel products on a large scale in Canada. The Government, it is understood, has not yet decided to bonus corporations desiring to engage in the work. Companies may, it is stated, submit a proposition and prices to the Government which will consider them and accept or reject them as it sees fit.

**Government Railways Will Have More Cars.** The Canadian Government railways are in need of seven million dollars' worth of extra rolling stock in addition to four million dollars' worth of equipment already contracted for. Officials of the railways are now discussing with the government methods for obtaining them. Of the seven millions, three millions are to be used for the purchase of passenger cars, and the remainder for box cars and a number of locomotives. The new equipment will not only be used on the government lines but will also be utilized to assist other lines which are at present hard up for equipments.

**Financiers Preparing for Peace.**—A great deal of careful thought is being given in the Street to the probable trend of events for a period of say six to nine months after the declaration of peace, and the general tendency is to look for very drastic readjustment in industrial and labor conditions. Many industries which depend on the war for their impetus must fade away, and it is a question of what developments will arise to fill the vacancy. Canada is in a hopeful position, having many of the raw materials which will be needed in the work of restoration, and it is one of our problems to rise to the occasion in that connection.

**Must Restrict Consumption of Gas in Ontario.**—The task of relieving the fuel crisis in Western Ontario caused by the inadequate supply of natural gas has been put up to T. A. Magrath, Dominion Fuel Controller. The Ontario Railway and Municipal Board, which conducted as extensive investigation a week ago into the situation in Sarnia, Windsor, Chatham and several of the border towns, has arrived at the conclusion that the situation can only be met by restricting the consumption of gas in radical fashion—by giving domestic consumers first call upon the supply. But the board, while convinced that domestic users should be supplied first, has found that it has not the power to interfere with contractual rights.

**Spruce Output for Airplanes to be Rushed.**—As far as governmental action is concerned, the Province of British Columbia has now gone the limit in the matter of speeding up to large proportions the supply of spruce necessary to the manufacture of airplanes for the Allied cause. An order-in-council passed by the provincial executive effectively links up the activities of the Imperial Munitions Board in this connection with an active and immediate co-operative policy advocated by the Brewster Government. The order grants powers to the government to arrange with the Imperial Munitions Board for the immediate logging of airplane spruce upon all vacant areas of crown land and calls upon such holders to proceed with the necessary operations forthwith.

**Niagara Falls, Ont.**—Ice is causing considerable trouble in the power companies' plants here which has created a shortage of power for the Hydro-Electric Commission. The Hydro secures its power from the Ontario Power Co., the Canadian Niagara Co. and the Electrical Development Co. All these companies have had trouble with ice. One day recently there was a shortage of from five to ten per cent on the power from the Ontario Power Co. As the total capacity of the machines of this company is 160,000 horse-power this meant a shortage of from 8,000 to 16,000 horse-power. The amount of power that was available fluctuated throughout the day and at intervals of ten minutes there was only 50,000 horse-power available.

**Canada Foundries & Forgings Have Good Year.**—At a meeting of directors of the Canada Foundries & Forgings Co., a concern having plants at Brockville and Welland, preliminary figures for the business of the year 1917 were submitted, and contained the evidence that the business of 1917 had considerably exceeded in volume that of 1916, while the profits for the year were fully equal to those of 1916. This was considered very satisfactory in view of the experience of many Canadian companies during the past year. The report respecting the Delaney plant at Buffalo fully justified the expectation of the directors and the plans they had in taking over the plant. The company has sufficient business booked to keep it busily occupied for the remainder of the year. The usual dividends were declared.

**May Construct Large Ships Only.**—It was stated at the Marine Department Ottawa on Monday that the Government is not contemplating the construction of vessels of 2,800 tons. It is hoped to start building ships before June 1, and the tonnage will likely be 5,000 and 8,200. Although arrangements for steel plates and other parts necessary in the construction of the ships have not yet been definitely settled, it is believed that these will be supplied through the British Purchasing Commission. It is understood that the Marine Department officials who visited Washington recently made an arrangement with the Commission to this effect. The ships will be owned by the Government, but their method of operation, the Marine Department states, has not yet been decided on.

**Could Produce Much More Coal.**—That the 10,000 miners of Nova Scotia could produce from 1,500 to 2,000 tons of coal more per day if "mechanical haulage" or more horses were used at the mines

to remove the "mine boxes," was the statement of S. Barrett, President of the Amalgamated Mine Workers of Nova Scotia, who arrived in Ottawa on Monday to attend the joint conference of Canada's Labor delegates with heads of the Government. Mr. Barrett explained that he had come to Ottawa at the invitation of the Government to talk over increased coal production. He stated that it was his intention to bring to the knowledge of the Government the mode of mining coal, and he would suggest that more up-to-date methods be employed than having the men push out the mine trucks.

**War Tyee Launched at Victoria.**—The wooden steamer War Tyee was successfully launched at the Cameron-Genoa Mills Shipbuilders, Ltd., Victoria, B.C., yards on Jan. 24. This vessel is the third of the boats building on the coast for the Imperial Munitions Board. She was christened by Mrs. Butchart, wife of R. P. Butchart, representative of the Imperial Munitions Board. The War Tyee is the same size as the War Songhee and War Nootka, being a standard type chosen by the board. The War Tyee is 250 feet long, 43 feet 6 inches beam, and 25 feet deep, with a deadweight capacity of 2,800 tons on a 21 feet draught. The machinery will be installed at the Ogden Point assembling plant. She will be equipped with triple expansion engines of 950 horse-power. The official trials of the War Tyee will probably be run about the middle of March.

**New Commissioners on Imperial Trade.**—A despatch from London, England, states that the changes recently announced among the trade commissioners result from the Dominion Royal Commission, one of the recommendations of that body being an increase in the number of representatives, and Canada being allotted four senior members. Newfoundland will also be covered under the new scheme and other appointments are expected shortly. Hamilton Wickes, who will remain at London Headquarters, spent five years in Montreal as senior commissioner. One important feature of the new arrangment is to keep on the London staff several commissioners with practical experience with trade conditions in the Empire. Provision is made for a division of the functions of the board into two main departments with several sub-departments, but the agitation for an Imperial Minister of Commerce is without prospect of success.

**Canadian General Electric Co.**—The fiscal year of the Canadian General Electric Co. was brought to a close with the end of December. Col. Frederic Nicholls, the president, states that the volume of business transacted during the 12 months in question compares favorably with the previous year. "While under present unsettled conditions it is difficul to look very far ahead," he adds, "the outlook is encouraging. The principal improvement effected by the company in 1917 was the fitting up of its Bridgeburg works at the Niagara River as a shipyard, which is now in operation for the purpose of constructing four

LANCO BALATA BELTING
LANCO BALATA BELTING
Is as nearly stretchless as is possible in a good belt.
On account of the impregnation process a very tightly woven duck can be used, which is partly responsible for the lack of stretch, but only partly. The impregnation of Balata Gum itself fills the pores of the strands of the duck and between the strands. As the duck is stretched during impregnation the gum keeps the fabric from contracting, and it remains in a stretched condition.

United States Government, and at its ... engaged in the production of 6-inch forg...

Steel Plant for Vancouver.—The Hon. ... Minister of Mines for B... Columbia, states that Vancouver ... the importance of a ... metallurgical centre and ... try. It is reported that the B.C. Provincial Government has been engaged in ... with eastern capitalists and ... local smelter owners. The negotiations have not reached a point where the government has agreed to join with the Pacific Steel Co. of Thorne, the Acton Iron and Steel Co. of Port Moody, in which companies the Tudhope interests of Orillia, Ont., and R. F. Turnbull, a well-known electrical metallurgist of Welland, Ont., are identified, together with other interested parties, in inviting an eminent outside metallurgist to visit Vancouver and make a final report on the proposal to establish a steel plant here. It is understood if the final report proves satisfactory the government will extend the company its aid and influence."

**Norwegians Would Build at the Coast.**—Developments in shipbuilding at the Coast may be looked for if negotiations now on with the Dominion Government come to anything. A delegation representing Norwegian interests has been conferring with the B. C. Manufacturers' Association and has expressed its willingness to go into shipbuilding at Vancouver providing the Dominion Government will give the necessary permission. One of the principals is a relative of Norway's finance minister and there is no doubt as to the capital. The trouble is that permission is refused to build vessels for neutral countries, but urgent pleas have been made to the government to raise this embargo on the ground that there are no further orders in sight after the fleet of twenty-seven wooden steamers for the Munitions Board is completed. If the necessary license is given the Norwegians will go ahead and establish a yard for the construction of steamers, and telegrams are now passing between Vancouver and Ottawa on this point.

## MARINE

**Equimalt, B.C.**—The British Columbia Salvage Co's. steamer Salvor has been docked at Yarrow's yard for a general overhaul.

**Vancouver, B.C.**—The Union Co.'s steamer Coquitlam has been hauled out at the B.C. Marine Co's. plant for annual inspection and overhaul.

Victoria, B.C.—The ... has left her moorings at the Foundation Co's. wharves at Point Hope and has gone to Ogden Point to have the boilers and engines, etc., installed.

**Vancouver, B.C.**—The executors of the ... Hendry estate have sold a site on ... Creek to John Coughlan & Sons, which will give the shipbuilders an additional 400 feet of frontage which they urgently need for the expansion of their business.

Victoria, B.C.—The auxiliary schooner Jean Steadman, eleventh of the fleet built for the Canada West Coast Navigation Co., is fitting out at Victoria and will run her trials some time this week. She is to load lumber for Australia at the Fraser River Mills and will do her trials while bound up from Victoria to the river. Captain Manning will be the master.

**Pictou, N.S.**—The Gaspesien has been towed into Pictou harbor and will remain here for the rest of the winter. The Gaspesien when bound from Montreal to New York was caught in the ... in No thumbe... and ... helpless for two weeks. Later she drifted down between Belle River and Point Prim being eventually released by the ice breaker Prince Edward Island.

## INCORPORATIONS

**Gas Processes Ltd.,** has been incorporated at Ottawa with a capital of $50,000 by W. A. J. Case, J. B. Taylor and G. E. Atwood, all of Toronto, to carry on the business of electrical, mechanical and gas engineers at Toronto.

## BOOK REVIEWS

**Heaton's Annual, 1918,** published by Heaton's Agency, Toronto, price $1.25. The fourteenth edition of this valuable reference work is just out, and as in the case of previous issues, contains a great deal of useful information for business men and also for the public generally. All the matter in last year's edition has been retained, including the Customs Tariff, Boards of Trade Register, Summary of Resources of all the provinces, and other interesting information. Of the new features we notice particularly the complete list of titled and decorated Canadians which the war has swelled to several pages, and under the heading of "Commerce" an interesting compilation of the pre-war imports from enemy countries into Canada, which will be a useful guide to firms considering the establishment of a new industry in the Dominion. At the end of the book a new section under the heading of "Colonization" gives some very interesting and valuable information, which has never before been collected, giving for each province land available for farming, fruit farming, cattle and sheep ranching, etc., crown land regulations, financial assistance of farmers by Provincial and Dominion Governments, special provisions for returned soldiers, etc. The widespread reputation of Heaton's Annual in Canada, Great Britain and the United States is due to the judgment which has been used in the selection of its contents by the editor. It is not a luxury, but a necessity, and no well-equipped office can afford to be without it. From cover to cover in its 450 pages there is nothing that the critic would eliminate.

# Canada's Place in the Markets of the World

By R. J. Younge*

*In the course of the following address [illegible] Canadian Manufacturers' Association, Maritime Provinces Branch, the speaker put three important questions to his audience, and the manner in which the answers were expounded possess [illegible] reading interest for all who have Canada [illegible] respective [illegible]*

THERE has been one predominant note throughout this convention. All the addresses have laid stress on the one fact—that no matter what other duties we have, the first and paramount duty of every Canadian is to do what he can to win the war. Nothing that I will say would detract from this principle that is being laid down so forcibly all over the Dominion. But I would like to say that, while we bend every ounce of energy we have towards winning the war, we should not neglect the next most important thing—the conditions after the war.

This is the special duty of Canada's business men who are not in the trenches. Everyone in Canada has some duty to perform which is connected in some important way with the great war, but let me impress upon you the fact that, if for some reason or other we are not in the trenches, it becomes our particular duty to support those who are and to prepare for the conditions which will follow when the men who are fighting return home. In pointing out this and in putting these future conditions plainly before you, I am not asking of you anything that the business men in Great Britain are not asked to do, I am not asking you to take up anything that the business men of France are not asked to do, I am not asking you to take up anything that the business men in the United States are not asked to do; and I leave it to yourselves whether the business men of Germany are not at this very moment thinking and planning for after-the-war trade. In short, the business men at home in all the belligerent countries are preparing for the future.

### When Munition Orders Cease

Let me ask you three important questions—first of all in connection with the change that must come when our munition orders are finished. We have to-day in Canada one thousand factories making shells and various kinds of requirements for the war. Employed in those factories there are half a million workmen. I ask you gentlemen, and you are all business men, what is going to happen to these factories when these munition orders are cut off, as they will be some day—soon, we hope; perhaps over night.

The second question is, how are we going to take care of our returned soldiers? We will have perhaps three or four hundred thousand soldiers coming back from the front, and all the manhood there is in us tells us that our first duty as Canadians is to see that employment is offered to these men. If we do not plan some scheme now, if we allow these intervening months to pass while they are away carrying the burden in the trenches, without preparing and organizing to insure them not only welcome when they come back, but a good job which will bring them proper remuneration, we shall have failed to do our duty.

But even supposing that we have orders to fill these factories, even supposing that we have plenty of work for all our soldiers who will come home—then let me ask you how are we as a nation going to meet our national obligations after the war, unless we build up a balance of trade by greater production and wider markets? We do not realize what our national debt is going to be when the war is over. The seven and one-half million of people in Canada can only avoid staggering under that debt if, as a nation, we are able to sell more than we buy—that is the only solution for meeting our national obligation.

### The Other Side of the Picture

All that I have said to you may appear more or less pessimistic. I do not intend that it should be so, but when we think seriously of these problems which are confronting us, we must face cold, hard facts. There is another side, however, to this picture. If these conditions which we must face as business men do appear to be almost insurmountable, there is a brighter side in the magnificent prospect which we have to establish ourselves as a much greater factor in the world's markets than we have been in the past. Speaking with a few hundred manufacturers as I have in the past two years, I have been told by many that we cannot compete with the world, that our export experience before the war has taught us that money can be lost in export trade as well as made, and that when compared with the much lower-priced labor in Great Britain and much more highly specialized industries in the United States, Canada is operating under enormous disadvantages. Now, gentlemen, if I can leave with you only one idea, let it be on this very point. The President of the National Association of Manufacturers, speaking more than a year ago, said that in the enormous changes that were taking place in the world's trade, the manufacturer in the United States would reap his full harvest from those changes only if he learned now to understand that

### "Old Things Have Passed Away

and all things have become new." If that is true for the highly specialized and highly capitalized manufacturer of the United States, then I say that it is even more true for the small and sometimes struggling manufacturer in the Dominion of Canada. Gentlemen, the sooner that we learn that the conditions which prevailed before the war are not the conditions that will prevail after the war—are not the conditions that will dominate the future—just so soon will we commence to appreciate our wonderful new opportunities.

When I say old things have passed away and all things have become new, I am not telling you any fancy fiction. You all know that the old channels of trade have been buried in the past, old scales of wages have passed away, the old surplus of labor has gone, old shipping conditions have passed away, old easy-going systems of taxation are gone—for your lifetime and mine, at least—old antiquated methods, party distinctions and political ideas have passed away, and all is new—new channels of trade, new sources of supply, new markets, new scales of wages, new shipping conditions new standards of efficiency, new political ideas, making the narrow, sordid aims of party subservient to the welfare of the nation.

These changes are much more significant than they appear to us now. The Britain of to-day is not the same old Britain of before the war. The France of to-day is a new France. The Russia that calls for deliverance and is to-day bursting the chains that have bound her for centuries is a new Russia. The Germany that, with bowed head and broken heart, will sign the greatest peace treaty which was ever signed, will be a new Germany—and who will say that Canada, with the losses that she has sustained, the sacrifices she has made, and the everlasting glory which has been won for her by her sons in battle, who will say that she will not emerge from this terrible trial a new and greater Canada?

### International Preferences

There are those who believe that after the war we will have international preferential tariffs which would be of the greatest assistance to manufacturers of this country. They predict that after the war we will have first of all an inner circle for the members of the family of the Empire, a British preference operating throughout all British Dominions; a second circle just outside of that for allied countries; a third circle outside of that for neutral countries, and a fourth and almost prohibitive circle for the productions of enemy countries. For the reconstruction of our trade and our fin-

*Joint Manager, Canadian Export Association.

ances, what a splendid assistance this would be! and I fully believe that preferences of some kind will come, if they do, we must be ready to reap the full advantage of them.

But supposing we get no tariff preference, are we to sit down and say, just because we are not going to get a preference, we are not going to organize our natural resources and our industrial strength, to show the world what we are and what we have? After all, and I have spent a great deal of time studying this very question, I believe that what we need most is a new confidence in ourselves, and a willingness and determination of the Canadian business men to say that they want world business and that they are going to get it.

It has been surprising to see the part that Canada has played industrially in the war—in fact, it has been one of the great surprises in the war. Many of us do not realize that every plant that has been making shells in this country has undergone an experience in the widespread knowledge of new processes, in accuracy, in precision in the study and use of metals, and, above all else, actual efficiency from the management down to the meanest workman. It is a proud thing for us to know, gentlemen, that the efficiency engineers who have visited our country and inspected the munition plants of Great Britain, have said that the Canadian plants are fully the equal of the plants across the sea, not only in the actual results, but in the efficiency with which these plants are managed. Our industrial progress since the beginning of the war has been so marked that it would have been impossible for the universities and technical schools of Canada to impart, in the course of many years, such a wealth of knowledge and experience as has been crowded into as many months.

### National Action

But all this progress will be in vain unless we can gather it up and nationalize it. Here we must take a lesson from the industrial success of Germany. Germany learned to do things nationally. Every source of production throughout the empire co-operated and took its place in the great plan which was to place her at the head of the world. Her farmers and her manufacturers, her banks, her railways, her steamship lines, and, behind them all, her government, working together to the one great end, which, had it not been inspired by Prussion militarism, would have made Germany a model for national and commercial progress. Canada must learn to act nationally, and her business men must show the way.

The share of the world's trade which will come to us depends altogether upon how we organize to get it. What is Canada doing to prepare herself for world trade? What are our manufacturers, and our banks and our Government doing to get ready for Canada's century? How much attention are you giving to this big question in your own business? Let me say to you now that unless we use these intervening months till the war is over organizing and consolidating our position, the coming of peace will find us absolutely unprepared.

We must organize at home and abroad.

We must demand national technical education.

We must increase the efficiency and perhaps the capacity of our plants. We must tell the world that we can produce, and we must seek out reliable agencies and channels of trade in every friendly foreign market to sell Canadian goods.

I am not one of those who believe that after the war we will see a great and universal trade depression. I believe that if you will analyze the manufacturing strength of the allied countries you will see to what extent after the war the allied countries must lean on Great Britain. Take staple commodities of life; with the exception of the United States, she is the only one of the allies capable of producing the manufactured products demanded by the buying nations of the world. It seems to me that after the war, when the world's stocks must be built up again—they are practically depleted now in most lines; when reconstruction must commence in Belgium, France, Serbia, Poland and Roumania—when that time comes Great Britain will only be able to fill a fraction of her orders. Demands will be made upon her by every allied country, and her own country is thirsty for goods of many varieties; but where must the surplus goods—the orders that Great Britain cannot fill—come from? There is only one outlet for those orders, and that is the North American Continent—the surplus orders must be filled in the United States and Canada, and just in proportion as we can organize now to get them ready, just in that proportion will Canada reap her share.

### War Orders vs. Export Orders

War orders are very different from export orders. War orders have been thrust upon us, and we have been commanded to use every ounce of energy that we have to increase our production and give the armies at the front all they need. But you will not have export orders thrust upon you; they will not fall from the skies—you will dig for them, and so I say again the whole key to the situation lies in organization, and, if we do not organize, we will surely fail.

In the United States over a year ago this whole question was up for discussion; they wanted an association to lay down broad lines for export business out of the United States and to provide a practical channel for carrying out an export programme. A number of the leading bankers and business men of the Eastern States came together and organized the American International Corporations, with a subscribed capital of fifty million dollars, of which one-half was paid up. Can you imagine what a tower of strength to the United States export trade this Association is? When they required ships to take their goods to South America, and were handicapped by the high rates of shipping, the Association bought four ships and paid four millions of dollars for them. The first annual statement shows a profit of nearly twenty per cent. on paid up capital in the first year of operation.

What are the manufacturers of Canada doing in a similar direction? Two years ago an appeal was made to them to subscribe one hundred thousand dollars to establish a National Export Association. Two years have passed and only about sixty thousand dollars have been subscribed. The business of the Association is now growing so fast that we require new members and additional capital. What we need most is increased effort and support from our manufacturers themselves, and unless that effort and support is forthcoming before the war is over, the manufacturers of Canada cannot hope to reap from the new trade conditions what they are really entitled to, and what it is possible for them to get.

### An Appeal for United Action

Gentlemen, the outline I have given to you of the world situation at the present time, and what it is possible for us to do, is not complete without the appeal that I wish to make to you for this young Association. We have had so many things to encourage us in that Association that it would be a pleasure if I could tell you of the opportunities that are not only opportunities to-day, but the foundations we are laying now in Australia, New Zealand, South Africa and England; and we hope later on to plant seeds for Canadian products in France, Belgium, Italy, and last, and perhaps greatest of all, in Russia. We can only do this through united action, so that it comes back after all to the question whether the Canadian manufacturer has got faith in himself, and whether he is willing to join his fellow manufacturers in this great national movement.

I thank you most sincerely for the patience with which you have listened to me. I trust you will not dismiss this subject until you have definitely decided that the opportunities are too great to be disregarded, the duty too clear and too insistent to be thrown aside, and finally that your hearty co-operation will be given in solving this problem which we must admit is of the greatest importance to Canada next to the winning of the war.

## FUELS OF CANADA

B. F. HAANEL, chief of the division of fuels and testing of the Dominion Department of Mines read a paper on "The Fuels of Canada" before the Canadian Society of Engineers, at Montreal on Jan. 22. Mr. Haanel prefaced his remarks by saying that Canadians were realizing that Canada was dependent on the American coal supply and was at the mercy of foreign strikes or industrial disorganization. Canada's supply of fuel might, therefore, be cut off at any moment. He continued:

"But there is even a more important factor which we must consider, namely, the necessity which may occur for the United States to keep her fuel within her own country. Such a situation may not arise for some time, but the indications are that we may have to meet such an emergency in the near future."

"Canada, to-day, is facing a fuel situation of great gravity, a situation which was not created by any special conditions in this country, but by those obtaining in the neighboring country. The United States is suffering from a shortage of fuels as a result of the withdrawal of skilled labor from the coal mines to other occupations, and, perhaps more directly, owing to the abnormal demand on the transportation facilities of that country for the carrying of material directly connected with the conduct of the war.

"We are not wholly dependent on the United States for our fuel supply, but we are dependent to the extent of 55 per cent. of our total coal requirements and 98½ per cent of our crude and refined oil products. Large and important sections of Canada, moreover, are almost wholly dependent on imported coal for house-heating purposes. This is a matter for grave reflections, since in a country such as ours, where artificial heat must be supplied during eight months of the year for the sole purpose of maintaining life, a continuous and dependable supply of fuel is absolutely essential.

"The present unsatisfactory—indeed alarming—situation can be improved only by a determined and energetic exploitation and utilization of our own vast fuel resources.

### Canada's Needs

"The total fuel requirements of this country during the year 1916 amounted to nearly 30,000,000 tons of coal; 299,426,121 imperial gallons of crude and refined oil products, and firewood valued approximately at $60,000,000.

"Compared with her annual requirements, Canada's production of fuels for the same period amounted to 14,483,395 tons of bituminous coal, of which 2,135,359 tons were exported; 6,934,288 imperial gallons of crude oil and wood fuel to the value of $60,000,000. To meet our own needs, therefore, it was necessary to import 17,580,603 tons of coal, and 292,426,131 imperial gallons of crude and refined oil products.

"Of this quantity of oil, approximately 50,000,000 gallons were used on the railroads; 30,000,000 gallons for steamships, and the remainder 210,000,000 gallons, was used for lighting and heating, in the form of kerosene and, to a large extent, in the form of gasoline, for power purposes."

### Canadian Fuel

The principal fuel resources of Canada, Mr. Haanel said, were bituminous and anthracite coal, lignites and peat. The coals were in the extreme east and west, the lignites were in Alberta and Saskatchewan, and within the limits of these deposits were 12,000 square miles of peat bogs.

Bituminous coal as such was of use only in industries, but an excellent substitute for anthracite, for domestic use could be produced from bituminous coal by a process of carbonization at low temperature and briquetting, which was in actual operation to-day. Lignite and peat required preliminary treatment before becoming available for general fuel purposes. If this treatment was given them the fuel situation would be greatly improved.

Mr. Haanel was of opinion that, at comparatively small outlay of money it would be possible to establish a commercial plant to demonstrate that the lignites could be converted into a fuel entirely satisfactory for domestic and industrial purposes.

As for peat resources, the speaker said that an economic process for the manufacture of raw peat into an excellent fuel for domestic and to some extent industrial purposes was in use to-day, and had been employed for many years in European countries, notably Russia.

"Not until the utilization of a natural substance is forced by absolute necessity," he said, "will the most sincere and earnest efforts be put forth to successfully and economically convert it into a usable product. It appears to me that the time is at hand when necessity will decide that we Canadians utilize our peat resources, and in the most efficient manner. . . . We not only have the process for manufacturing peat fuel, but also sufficient detailed information concerning peat bogs of immediate importance to make a good start in the formation of a peat industry. . . . Seven bogs, conveniently situated with respect to Toronto, could supply that city with 26,500,000 tons of fuel, and seven bogs, within easy reach of Montreal, could supply 23,500,000 tons.

### Must Exploit

"The fuel situation in Canada, as I view it, is not a gloomy or a discouraging one, for we are endowed with fuel deposits on a magnificent scale. All that is necessary now is that proper exploitation and economic use be assured."

## ST. JOHN AS A WORLD PORT

THE strategic value of the port of St. John as a factor in the winning of the war and in the national progress and development which is to follow the close of the struggle is a matter that should receive the careful attention of all who have any interest in the port, locally or nationally.

It did not need the war to emphasize the importance of St. John as a national port, or its value as a port of interchange for ocean and inland traffic. This was demonstrated long before the war broke out, the total volume of port trade having increased from $14,000,000 in 1900 to slightly over $30,000,000 in 1914.

### Record Annual Trade

Since the opening of the war the trade of the port has leaped to over $206,000,000 in one year, a record of progress surpassed by only one other port in Canada.

This was largely due to the fact that the Imperial authorities were quick to recognize its strategic value.

Though the record of Imperial shipments on war account through the port has not been given to the public in detail, the official records show that from December, 1915, to September, 1917, 1,232,687 tons of Imperial supplies were shipped through this port and 687,147 tons through its sister port of Halifax. For the corresponding period 1914-16 the totals were 538,937 tons for St. John, and 356,198 tons for Halifax, the increases at the two ports being 693,750 tons for St. John and 330,949 tons for Halifax. These figures are exclusive of the commercial exports of the ports mentioned.

A presentation of these figures must impress upon the public the vast potentialities of St. John as a factor in the war struggle and the great importance of maintaining it in the highest degree of efficiency.

### Value of Location

Men and munitions and food supplies are very necessary factors in the prosecution of war, but in the world struggle of to-day strategic ports through which troops and supplies may be forwarded with the least possible delay and with the minimum of danger are quite as important an essential.

Hitherto St. John has been chiefly used as a port of shipment for men and supplies from Canada, but with a growing scarcity of available tonnage and the necessity of saving every moment of time on the ocean voyage the nearness of this port to Great Britain and France suggests the possibility of it being used for the embarkation of U.S. supplies, provided the equipment of connecting railways would permit of this arrangement.

A glance at the table of ocean distances emphasizes the strategic position of St. John as an ocean port.

### Ocean Distances

| | To Liverpool miles | To Havre miles |
|---|---|---|
| St. John | 2,692 | 2,813 |
| Portland, Me. | 2,776 | 2,871 |
| Boston | 2,854 | 2,949 |
| New York | 3,043 | 3,131 |
| Philadelphia | 3,172 | 3,267 |
| Baltimore | 3,328 | 3,423 |
| Charleston | 3,518 | 3,631 |

This means that with shorter ocean voyages more men and more supplies could be shipped overseas through St. John than through any of the Atlantic ports of the United States, thus reducing the number of ships that would be required, limiting the ocean perils to a minimum, and hastening the winning of the war.

In this view the "Board of Trade Journal" is supported by such an excellent authority as Premier Lloyd George, of Great Britain, who declared in a recent address: "We must use our shipping to ply between ports between which the voyage will not occupy a long time."

# American Engine Builders Restore Damaged Ships

Special Correspondence *

*Sinister meaning is indeed a mild term to use in describing the malicious damage done by their crews to German ships in American harbors when it was seen that war was becoming inevitable. All the resources of the world were utilized on a wholesale scale, and the skill, ingenuity and efficiency exhibited by U. S. engineers are a matter for congratulation and mutual satisfaction amongst the Allied nations at this time.*

All the German and 11 [illegible] ships by their crews, prior to their seizure by the United States Government when war was declared, have been recovered and these ships are to lay [illegible] tonnage to the transport cargo fleets in war service for the United States.

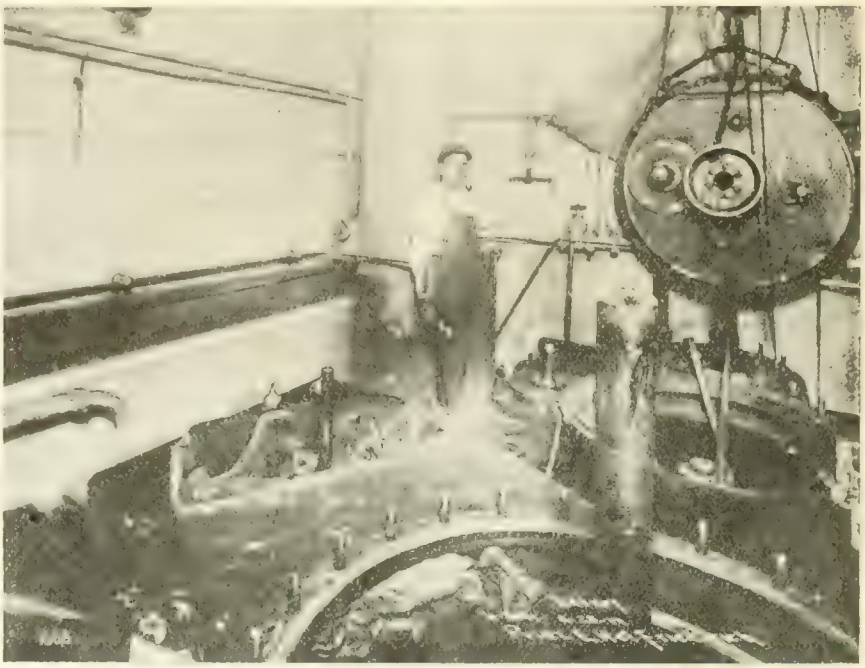
[illegible] central authority gave an order for destruction on these ships, effective on or about February 1, 1917, simultaneous with the date set for unrestricted submarine warfare and that the purpose was to inflict such vital damage to the machinery of all German ships in our ports that none could be operated for from 18 months to 2 years.

### German Purpose Signally Defeated

This purpose has been defeated in signal fashion. In less than eight months all the ships were in service.

The destructive campaign of the German crews cunningly comprehended a [illegible] parts they believed would necessitate the shipping of new machinery to substitute for that which was ruthlessly battered down or painstakingly damaged by drilling or dismantlement. There is documentary proof that the enemy believed the damage irreparable.

To obtain new machinery would have entailed a prolonged process of design, manufacture, and installation. Urged by the necessity of conserving time the engineers of the Navy Department succeeded, by unique means, in patching and welding the broken parts and replacing all of the standard parts which the Germans detached from their engines and destroyed or threw overboard.



BROKEN VALVE CHEST AND SCORED PISTON ROD OF THE OSTWEGO, FORMERLY THE PRINZ EITEL FRIEDRICH.

Copyright by Committee on Public Information

* [illegible] Committee on Public Information, Washington, D.C.

[illegible] THE KAISER WILHELM DER GROSSE WAS CRACKED [illegible]

### Scheme of Ruin Shrewdly Devised

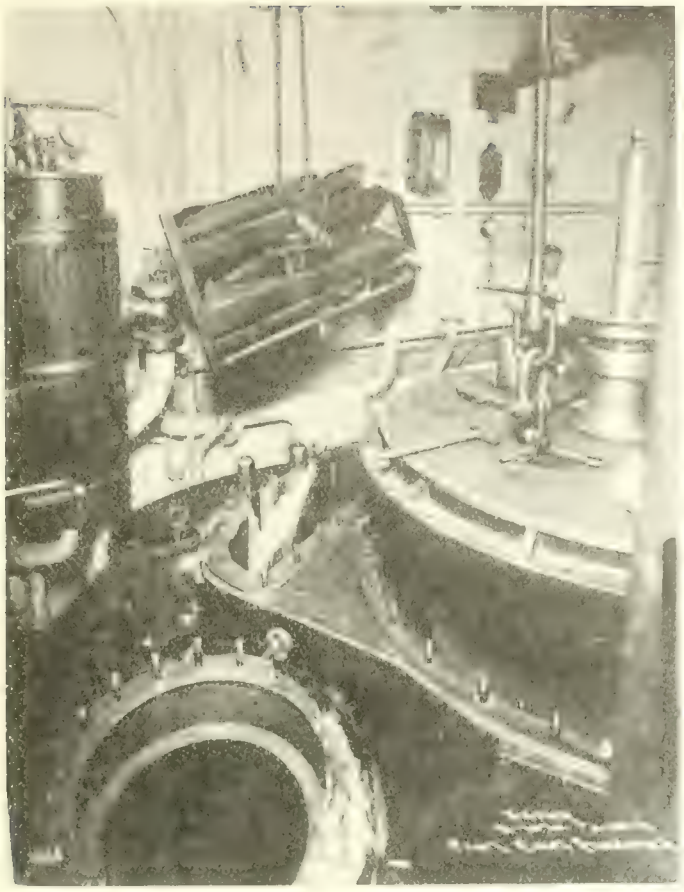
The mechanical evidence is that the campaign of destruction was operated on these ships for more than two months and that the Germans were convinced that they were making a thorough job of it. Their scheme of ruin was shrewdly devised, deliberately executed, and it ranged from the plugging of steam pipes to the utter demolition of boilers by dry firing.

When the United States Shipping Board experts first surveyed the ruin the belief was expressed that much new machinery would have to be designed, manufactured, and installed, making 18 months a fair minimum estimate of the time required. However, at the Navy Department, where the need of troop and cargo ships was an urgent issue, officers of the Bureau of Steam Engineering, having faith that the major portion of the repairs could be accomplished by patching and welding, declared it was possible to clear the ships for service by Christmas, and the last of the fleet actually took her final sea test and was ordered into service as a Thanksgiving gift to the nation.

### Special Workmen on the Job

To accomplish this end the Navy Department secured the services of all available machinery welders and patchers, many of them having been voluntarily offered by the railroads.

Although explosives were not used in the process of destruction, the engineers of the Navy Department were always conscious of the danger of hidden charges of high explosives which might become operative and disastrous when the machinery was put to a test. Instances of artful pipe plugging, of concealing steel nuts and bolts in delicate cylinders, of depositing ground glass in oil pipes and bearings, of cunningly changing indicators, of filling fire extinguishers with gasoline and similar means of spoliation, were common enough to induce the engineers to make a rule calling for thorough overhauling. On each ship there was no boiler that was not threaded through every pipe for evidence of plugging, no mechanism of any sort that was not completely dismantled, inspected, and reassembled before it was finally passed as safe.



BROKEN VALVE BROKEN VALVE CHEST AND BROKEN FLANGE ON THE OSTWEGO, FORMERLY THE PRINZ EITEL FRIEDRICH OF HAMBURG-AMERICAN LINE
Copyright by Committee on Public Information

**Record of Damage Found on One Ship**

A memorandum written in German was picked up on one of the ships which gave a complete record of the destruction on that ship. Investigation revealed that the list, which had evidently been left through an oversight, was correct in every detail. The following is a translation of excerpts from this memorandum:

"Starboard and port high pressure cylinder with valve chest: Upper exhaust outlet flange broken off (can not be repaired)."

"Starboard and port second intermediate pressure valve chest: Steam inlet flange broken off (can not be repaired)."

"First intermediate pressure starboard: Exhaust pipe of exhaust line to second intermediate pressure flange broken off (can not be repaired)."

"Starboard and port low pressure exhaust pipe damaged (can not be repaired)."

The parenthetical optimism of the German who was so confident of the thoroughness of his mutilation is now the source of much glee among naval engineers, inasmuch as every one of the supposedly irreparable parts was in fact speedily repaired and those engines are to-day as powerful and serviceable as when they left the hands of their makers.

The method of patching and welding broken marine engines had never before been practised, although the art has been known in the railroad industry for 15 years. Three methods of patching were used; electric welding, oxy-acetylene welding, and ordinary mechanical patching, the latter often later being welded. Following the repairs tests of the machinery were first made at the docks, where the ships were lashed firmly to the piers while the propellers were driven at low speed; and later each ship was taken to sea for vigorous trial tests. The patches and welds were reported as having given complete satisfaction.

When the Leviathan, formerly the Vaterland and the largest ship afloat was put into commission by the United States Government and sent to sea for a trial run, her commander, a young American naval officer, was ordered to "exert every pound of pressure that she possesses, for if there is any fault we want to know it now." The Leviathan stood the test. She was one of the ships least mutilated, due to the fact that she was in bad repair and it was believed that she would not be fit to put to sea for many months. The navy engineers found it necessary to overhaul and partially redesign and reconstruct many important parts of the engines.

| Adelheid | (No name.) |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| Calabaria | (No name.) |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible] |
| [illegible] | [illegible]

many instances. Numerous fire extinguishers were found to be filled with kerosene and gasoline. Piles of shavings and refuse were strewn about where fires might be started, open cans of kerosene being found in several of these incendiary traps. There had evidently been a plan to burn the ships under certain conditions and it is believed that the German crews were seized and interned somewhat in advance of their expectations.

### Case of Vaterland Distinctive

The case of the Vaterland was quite different from that of any other ship. Engineers of the Navy Department who examined the big liner declared that inferior engineering had been practised in her construction. She has four turbine engines ahead and four astern on four shafts. All of the head engines were found in good condition and all of the astern engines were found damaged.

The major portion of the damage was credited more to faulty operation than to malicious intent. Cracks were found in the casing of the starboard high-pressure backing turbine of such size as to make it certain that the engine had not been used on the vessel's last run. Certain documentary evidence found on the ship corroborated this belief. It also indicated that the Vaterland on her last trip had made less than 20 knots.

There was just enough evidence of mutilation to warrant full investigation and the vast mass of machinery, electric apparatus, and piping in the Vaterland was patiently and doggedly examined before she was sent to sea. Original defects in her engine equipment were corrected, she was overhauled and in many respects refitted, and on the whole she was declared a better ship when she entered the service of the United States than when she took her maiden voyage.

THE general practice in regard to the use of water for internal grinding is to grind soft steel and hardened work wet, and to grind cast iron, bronze, etc., dry.

## OFFICIAL NARRATIVE OF GERMAN U-BOAT SINKING BY U.S. DESTROYERS

THE event related below took place in November last and resulted in the destruction of a German submarine and the capture of the crew by American destroyers. According to an official [illegible] ment recently made by Secretary Daniels, the capture was made by the U.S.S. Fanning, assisted by the U.S.S. Nicholson. The Fanning was commanded by Lieut. A. S. Carpender, Lieut. G. H. Fort being the executive officer.

About 4.10 p.m., while escorting a convoy, the lookout of the Fanning, Coxswain David D. Loomis, sighted a small periscope about a foot above water some distance off the port bow. The periscope was visible for only a few seconds. The destroyer immediately headed for the spot and three minutes after the periscope had been sighted dropped a depth charge. The Nicholson also speeded to the position of the submarine, which appeared to be headed towards a merchant vessel in the convoy and dropped another depth charge. At that moment the conning tower of the U-boat came to the surface between the Nicholson and the convoy. The Nicholson fired three shots from her stern gun. The bow of the submarine came up rapidly. She was down by the stern, but righted herself and seemed to increase her speed. As the Nicholson cleared, the Fanning headed for the U-boat, firing from the bow gun. After the third shot the crew of the submarine all came on deck and held up their hands, the submarine surrendering at 4.28 p.m.

#### Submarine Goes Down

The Fanning approached the submarine to pick up the prisoners, both destroyers keeping their batteries trained on the boat. A line was got to the submarine, but in a few minutes she sank, the line was let go and the crew of the U-boat jumped into the water and swam to the Fanning.

Although the crew all wore life preservers, a number of them were exhausted when they reached the side of the destroyer. As the submarine sank, five or six men were caught by the radio aerial and carried below the surface before they disentangled themselves. Ten of the men were so weak that lines had to be passed under their arms to haul them aboard. One man was in such a condition that he could not even hold the line thrown him. Chief Pharmacist's Mate Elzer Harwell and Coxswain Francis G. Connor (N. N. V.), jumped overboard after this man and secured a line under his arms. When he was hauled aboard every effort was made to resuscitate him, but he died in a few minutes. The four officers of the submarine and the 35 members of the crew were all taken prisoners.

After being taken on board the prisoners were given hot coffee and sandwiches. Though kept under strict guard, they seemed contented and after a short time commenced to sing. To make them comfortable the crew of the destroyer gave them their warm coats and heavy clothing.

The German officers said the first depth charge had wrecked the machinery of the submarine and caused her to sink to a considerable depth.

The submarine bore no number nor distinguishing marks. She was identified by life belts and by statements of an officer and men of the crew. One of the life belts had "Kaiser" marked on one side and "Gott" on the other.

## NOTES ON EXPORT PRACTICE

By "Commerce."

IN connection with the f.o.b., f.a.s. and c.i.f. clauses in quotations on goods intended for the export market considerable misunderstanding sometimes arises. We frequently see the term "F.o.b. factory," which means little or nothing to the foreign buyer except that the seller is not particularly anxious for the business or he would take the trouble to give his customer any accurate idea of what the goods will actually cost him when delivered. F.o.b. meaning "free on board," should only be used in connection with export business where the goods are actually delivered stowed in the hold of the vessel. F.a.s. signifies "free alongside," and is somewhat vague in meaning, as it might indicate that demurrage charges on the cars or lighters were up to the buyer. Strictly speaking, this term is the same as f.o.b. minus all dock and loading charges, cranage, primage, etc.

### By Way of Illustration

Let us take the case of a manufacturer of woodworking machinery in Toronto quoting against an inquiry from Buenos Aires. A regular line of steamers runs from both New York and Philadelphia, and one of these ports would provide the best route. There are several ways in which the quotation might be made:

**F.o.b. Toronto.**—This phrase implies, though it does not actually state, that the shipment will be loaded on cars routed for New York or Philadelphia. Every kind of charge, such as rail, freight, insurance, dock charges and all subsequent costs, are to be borne by the buyer. Now it is easy to see that the South American importer will have a most painful time figuring out just what this machinery will cost him by the time it is installed in his factory.

**F.a.s. New York.**—In this case the shipper undertakes to pay rail freight and lighterage right into the steamship dock. In the case of goods arriving in New York on the Jersey shore, they are lightered across to the steamship dock free of charge by the railway company; nevertheless it is often more convenient and quicker for the shipper to make his own arrangements with a private lighterage company to handle these goods across the North River. However, in either case the charges are all up to the seller of the machines until the cases are placed upon the pier.

**F.o.b. Steamer, New York.**—This is certainly the most satisfactory way to make quotations, as both parties know exactly how far each is liable. The shipper has to have the goods stowed in the hold, as shown by the bill of lading, which is recognized by the bank as a negotiable receipt for the shipment. In quoting on this basis the seller should add to his offer three important pieces of information:

(i.) Size and number of cases.
(ii.) Prevailing freight rate.
(iii.) Prevailing marine insurance rate.

On this basis the foreign buyer can tell exactly what the machinery is going to cost him laid down by simple addition.

### Increased Responsibility

**C.i.f. Buenos Aires.**—Quoting on this basis carries the responsibility of the shipper a little farther. Cost, insurance and freight to Buenos Aires means exactly what it says. However, there is sometimes a little misunderstanding in regard to the marine insurance. Shippers sometimes imagine that because they contract to insure the shipment up to the port of arrival that they are liable for its safe transit. Nothing, of course, is farther from the truth; the shippers' responsibility ceases as soon as the goods are stowed in the hold, exactly as in the case of an f.o.b. sale. In addition, he merely contracts to pay the ocean freight and insurance to destination. We are considering the case of a shipment to the Argentine and the laws of the republic hold that the insurance in this case must include war risk. Now in shipments to most other countries at the present time it is legitimate for the shipper to add the war risk premium to his invoices, but not in the case of the Argentine. Certain Customs authorities call for a definite certified statement of the freight charges on the invoice; this is necessary to enable them to estimate the "home market value" of the goods and to arrive at the ad valorem duty. It is always wise to include such a statement, whether specifically required or not.

**F.o.b. Buenos Aires.**—The buyer will sometimes request all quotations to be put in this form. It would not, however, be to the advantage of any shipper to quote f.o.b. destination, because the phrase is too elastic and might include many large and unforeseen charges. It would certainly be held to cover duty and cost of unloading, sundry Customs charges and cartage or teaming. The best alternative would be for the shipper to quote c.i.f. and leave all such local charges to the buyer.

### Export Licenses

At the present time all the great exporting countries have embargoes in force covering practically all metals and manufactures of metal. The embargo is designed primarily to keep such material out of enemy countries and further to control the output in the event of there being a shortage of the commodity. Where good reason exists and there is no shortage export licenses or permits are issued to approved persons at the discretion of the authorities. In Canada the Chief Commissioner of Customs at Ottawa issues a license to approved firms for the export to allied countries of embargoed metals and manufactures, provided that a declaration is produced from both the shipper and the buyer that the material will in no case be converted to enemy use. This license attached to the export documents is scrutinized by the Customs officer at the point of export and the inspector has authority to hold any shipments not properly described or covered by a license.

A similar arrangement is in force in the United States. In respect of iron or steel in various forms the embargo is more complete, as no licenses are being issued for the export of these goods unless it is shown that they are primarily intended for the manufacture, directly or indirectly, of war material for the allies. Other materials, such as non-ferrous metals, oil, gasoline, coal and coke, fertilizers and explosives, may be exported for ordinary industrial use subject to license, but, of course, in the event of any shortage becoming apparent the same restrictions would probably be applied as already cover iron and steel. Permits for the export of these goods to Canada are to be obtained on application to the Division of Export Licenses, 1435 K Street, Washington, D.C. Any attempt to evade this law renders the parties concerned to a fine of $10,000, or two years' imprisonment, so it will be seen that the Washington Government is taking a very strong stand against the possible shipment of goods for enemy use.

In Great Britain controllers have been appointed to deal with different raw materials, and each of them has authority to issue permits for the export of his particular commodity, provided (i.) that a surplus of such material exists in the country, and (ii.) that shipping space is available for its transport. The chief difficulty which arises is that a machine or other article contains materials coming into the province of two or more different controllers, in which case it is not easy to obtain the endorsation of all these different officials to the same permit.

## INCREASED USE OF "ISHERWOOD" SYSTEM OF SHIP CONSTRUCTION

ACCORDING to a recent statement issued by J. W. Isherwood, of London, Eng., an increase in the number of ships contracted for under his system of construction is recorded during the past year, despite the almost total abolition of building for private ownership.

No less than 180 vessels, aggregating in deadweight carrying capacity about 1,334,000 tons, have been placed since the end of 1916. The grand total now stands at 800 vessels, aggregating 6,000,000 tons deadweight carrying capacity, as against 6 vessels, aggregating 31,608 tons in 1908. Of the 800 ships referred to, there are 386 general cargo vessels, colliers and ore steamers, and passenger vessels aggregating 2,891,600 tons deadweight carrying capacity, 24 Great Lakes freighters for 279,600 tons, 310 oil-tank steamers for 2,800,000 tons, 77 barges for 26,800 tons, 2 dredgers for 760 gross register tons, and 1 trawler for 570 gross register tons. The use of the system is greatly on the increase in the United States and in Japan.

# Canadian Mnfrs. Face Their Greatest Opportunity

By James W. Spence *

*Whatever [illegible] the war, it is and has been the [illegible] conclusion that international trade will be looked to as one of the most potent factors in the reconstruction period of the world. At the present time ample preparations with complete organizations are a source of much activity in the leading nations and should be [illegible]*

TO-DAY an opportunity presents itself to our manufacturers in foreign fields. Each mail from our allied countries brings forth many inquiries for materials of the Canadian manufacturers; but are we taking advantage of the opportunity to place our goods in such fields? Many articles have been written telling the manufacturers how to approach foreign trade without first establishing the first principles.

To-day very few firms selling to our foreign buyers would think of starting that most important department without first engaging a highly experienced man capable of handling such a department, and who is well versed with the various details necessary to do the work properly. They would not use book knowledge. These means were very acceptable to some before the war, but to-day very few manufacturers are looking for new business, so they are, therefore, losing the splendid opportunity for future business. Heretofore, it has been necessary to spend thousands of dollars on salesmen sent to these countries to drum up trade. To-day the business is sent to our doors and the great majority of us turn it away.

The remedy is a simple one. If we to-day do not plan and arrange for the use of the numerous plants that will some day be idle it is our own fault. Let us attend to our war needs, but at the same time let us look into the future for Canada and Canadian manufacturers.

We have all had a small sample of what conditions will be as soon as war contracts cease. Only a few months back, when contracts were not so freely given out, many valued employees lost their positions. Imagine what the conditions of the country will be when the time comes to change! We owe it to everyone to be ready.

We stated that the remedy is simple. IT IS.

Why not place for foreign trade a percentage of our products, say, 10 per cent.?, and they will be gladly accepted.

Place yourself, for instance, in a foreign buyer's position. He requires certain materials, foodstuffs, etc.; he sends his inquiries broadcast to the various countries. Some supply, others do not. Isn't it logical that this buyer will remember later, when we are all looking for business, those who helped when help was needed? It will not make any difference whether you supply his total requirements or merely some. Place your goods before them. Our materials will be remembered. They will advertise themselves and will be called for later when we need business.

We must remember, however, that the excess profit must be forgotten. The time is coming when we shall not speak so readily of the millions of dollars, but with very little arranging of our present plants we can very easily start now to lay the foundation for a staple lasting business.

On the manufacturers of to-day rests the welfare of the country of to-morrow. Unless the manufacturers prepare to-day, on their shoulders rests the idleness of our returned men.

The shops of to-day, that will be closed to-morrow, will stay closed for quite some time. Perhaps some of the manufacturers are unable to determine just what line to turn to for future manufacturing. If they will but consult with our Government and learn the requirements from foreign fields, which are easily obtained, they would have no trouble in reaching a decision.

Perhaps now would be a good time for the Government to step in and assist financially those who require it. Let the manufacturers set aside 10 per cent. of their plants for foreign work and let the Government assist in every way possible, both in advice and financially, and allot shopping space.

The future will show the advisability of early preparation. Our materials will advertise themselves and future business for Canadian manufacturers will be assured. In any event it deserves our most earnest consideration.

*Let us not forget the supposed war profits, as a great many of the war profits are only a supposition anyway.*

*Let us get at the remedy and put the Canadian products before that most acceptable market.*

*Let us start by placing an obligation on our foreign buyers. Very few of us forget an old favour, and least of all those whom we helped in the present crisis.*

*Let us place some of the burden on the other fellow by placing ourselves where he will not forget us when all the world will be out in competition for business.*

*Let our products be known so we shall not have to spend so much introducing them.*

*Let us prepare to turn our plants, mills and factories into the uses as soon as the war ceases.*

*President, the Spence Company, Ltd., Montreal.

## IMPERIAL TRADE PREFERENCE

CANADIAN bank managers in London, England, express lively interest in pronouncements of leading British bankers in favor of measures to create inter-Imperial trade preference through the establishing of rates of exchange within the Empire.

If feasible it may prove a greater stimulant of Empire commerce even than tariff preferences which the British Government have now followed the example of Canada and other Dominions in making a permanent feature of British policy.

Frederick Goodenough, chairman of Barclay's Bank, said: "The extension of banking organizations and the maintenance of fixed rates of exchange within the British Empire will give the Dominions and Colonies a substantial preference which would serve to consolidate and promote trade within the Empire and induce economy in the use of gold and enable gold resources to be utilized elsewhere. Drafts on London at fixed rates would be obtainable at all points. Similarly London would sell in the same manner and the balance of trade within the Empire would be adjusted by closer administration of inter-Imperial finance."

Mr. Goodenough announced that in view of greatly enlarged trade after the war, Barclay's Bank had arranged with the Colonial Bank, of which Lord Beaverbrook is president, for working together on joint account in financing exports and imports from and to the West Indies, West Africa, and elsewhere.

Charles Milburn, president of the London Joint Stock Bank, strongly urges increased gold production within the Empire to rectify the disproportion of gold to war liabilities. Canada has her share of sixty million sterling of Empire gold out of the world's total output of 95 millions.

Mr. Milburn said he foresees the development of a firmly united Empire which will carry and ultimately pay off the war debt, heavy though it is, but sound banking must have an adequate gold basis.

## ATLANTIC CONFERENCE FORMED

ACCORDING to an official announcement [illegible] steamship lines interested in the North Atlantic trade have concluded an alliance for the purpose of governing the [illegible] ing to an official announcement. The [illegible] but from which the German and Austrian lines are now excluded. The main offices of the organization will be in Paris.

The formation of the new "Conference" may be taken as a definite and far-reaching step towards an after-war shipping policy in which the Entente Allies do not propose to allow Germany to dictate. The old pre-war Atlantic Conference had its offices at Jena, in the heart of Germany, and it held most of its meetings in Berlin and Cologne. The new conference will consist, for the present, only of British, American and French lines. German and Austrian lines are excluded, and no neutral lines have yet been admitted.

The underlying idea of the organizaton is protective. A representative of the conference, in a talk with the newspapermen here, said that "the primary object is to consolidate, in a commercial sense, the interest of the allies, who have stood shoulder to shoulder in the war. We must have everything ready when peace is declared to endeavor to conserve business to the alles and to keep control of the Atlantic trade. We know what we have had to suffer in the past through the insidious German penetration, and how the German lines worked always to the prejudice of other nationalities in spite of their agreements."

The new organization will co-operate with various sectional conferences which are already in existence, such as the Trans-Atlantic Passenger Conference in New York, and the Mediterranean-Atlantic Conference, which includes mainly Italian and British lines.

The Atlantic Conference, as at present constituted, includes the following lines: Cunard, White Star, Allan, Canadian Pacific, Anchor, Anchor-Donaldson and Dominion (British); American Line (American); Compagnie Generale Trans-Atlantique (French).

## RESEARCHES ON TIN AND TUNGSTEN

THE *Board of Trade Journal*, London, England, says that one of the most attractive fields for investigation being opened by the exigencies of the war is that which pertains to the winning of tin and tungsten. Recently some successful experiments have been made with a view to increasing the recovery of tin. No systematic researches, however, have been undertaken beyond those designed to improve the appliances now in use; and, having regard to this fact, the Privy Council Committee for Scientific and Industrial Research has expressed the hope that a research association might be established in order that the series of investigations already undertaken might be continued with fresh vigor on a larger scale.

One of the difficulties in the way hitherto has been the want of adequate funds for sustained investigation and experimental trials. But the Ministry of Munitions, represented by the department for the development of mineral resources, is now venturing on a strong effort to make progress possible, and is suggesting that those interested in the tin and tungsten mines of Cornwall and Devon should co-operate in the establishment of a research association, and contribute to a central fund devoted to a study of the many-sided aspects of the problem. In this way adequate means might be provided annually for two or three years; and with such a fund, supplemented if necessary by a grant from the Committee of the Privy Council, experimental researches upon scientific principles could be conducted under the continuous supervision of first-class professional men, and upon a basis of cost which individual operators do not feel themselves able to bear.

This proposal is one which should appeal to mining companies and royalty owners from a strictly business standpoint. Under present methods over 35 per cent. of tin, and a higher percentage of wolfram, in the ore is lost. An improvement of even 10 per cent. in the recovery would have a very important bearing on the fortunes of the mines now being worked, and would, moreover, offer a considerable incentive for the resuscitation of many properties that have been closed down.

## INCREASED TRAFFIC AND FEWER SLIDES ON PANAMA CANAL

TRAFFIC through the Panama Canal last year increased largely over the previous years, according to the annual report of Col. Chester Harding, governor of the canal. A total of 1,876 vessels of all classes passed through the canal from July 1, 1916, to June 30, 1917, inclusive.

Of these, 905 passed from the Atlantic to the Pacific, and 971 from the Pacific to the Atlantic. In the fiscal year 1915, 1,088 vessels passed through the canal, and in 1916, 787. The total number of vessels transiting the canal since it opened for commercial traffic in August, 1914, is 3,751. The total net tonnage, canal measurements, for the several years is as follows: 1915, 3,849,035; 1916, 2,479,762; and 1917, 6,009,358. The cargo tonnage transported was, for 1915, 4,969,792; 1916, 3,140,046; and 1917, 7,229,255.

### Loss From Present Traffic Rules

The traffic for the year yielded a revenue of $5,631,781.66 from tolls. The rules for levying tolls have thus far remained unchanged.

It will be remembered, says the report, that under present law and regulation tolls are based on canal tonnage, at the rate of $1.20 per net ton, except when this product exceeds the registered net tonnage, United States rules, at a rate of $1.25 per ton, in which case the lesser amount is collected. The confusion, lack of uniformity, and loss in revenue to the canal resulting from the present arrangement have been fully discussed in previous reports, and remedial legislation is now pending in Congress.

In this connection, attention is invited to the fact that the revenues from tolls for the past fiscal year would have been $6,668,247.32 if canal rules alone had governed, which is $1,036,465.66 more than the amount actually collected.

### Dredging Work of the Year

The year's dredging chargeable to construction, which includes all the excavation in the canal prism at locations where the full widths and depths have not been once obtained is as follows: Gaillard Cut, 183,904 cubic yards; between Gamboa and Pedro Miguel Lock, 246,998 cubic yards; and Pacific entrance, 221,138 cubic yards. At the end of the year there remained 1,409,140 cubic yards of original excavation to be done within the limits of the canal prism.

Cucaracha slide has given no further trouble since the large movement that blocked the canal in August, 1916, as described in the report of last year. To reduce the chances of interruptions to traffic due to future similar movements if they occur, the material in the slide was removed for a distance of 100 feet outside the canal prism.

It is believed that in the future the great slides of the canal will be of historic interest only.

## SEVENTY OCCUPATIONS TAUGHT IN MONTREAL

AT the present time in Montreal there are 175 re-educational courses given to returned soldiers comprising instruction in seventy different occupations. The policy of the Military Hospitals Commission, to combine instruction under competent teachers selected from returned officers, N.C.O's and men, with the practical instruction under practical conditions has been found to work most satisfactorily indeed, the marked interest displayed by the men and their ambition to succeed is a constant inspiration to the teaching staff. The great willingness of manufacturers to co-operate with the vocational department in giving over their plant facilities for instructional purposes indicates clearly the wonderful appreciation of the services rendered by returned men at the front, and the importance of the great economic problem which confronts the nation.

THE tags attached to grinding wheels should be preserved, so as to enable duplicates of good wheels to be easily secured, as without that information it becomes necessary to guess and try different grades and grits to again secure the most satisfactory wheel.

# Constructing Fabricated Ships on Manufacturing Lines*

By R. H. M. Robinson **

*A timely discussion and explanation of [illegible] construction not previously attempted in any country and a historical resume of the development of the fabricated ship with the author's personal instructive [illegible]. The practical difficulties and the manner in which they were overcome promise interesting developments in the future.*

RECENTLY the term "fabricated ships" has become one of public interest. A fabricated ship may be defined, briefly, as a ship on which the work of punching and shaping the plates and shapes and, to some extent, assembling the riveting, is done in a fabricating shop, ordinarily employed for bridge or tank work, as distinguished from the usual practice of doing it in a shipyard punch shop. So far as the writer knows, the fabricated ship is a product of American progressiveness. The writer claims no credit for the idea or for its development, and hardly knows why he should prepare a paper on the subject unless it be that he has the honor to be connected with two companies now constructing ships on this system, one of which may reasonably claim to be the first to do so. The principal credit for carrying out the fabricating idea is due to Mr. C. P. M Jack, now consulting engineer, and to Mr. Max Willemstyn, engineering manager of the Chester Shipbuilding Company and of the Merchant Shipbuilding Corporation, and it would be improper to neglect to state that the ideas of Messrs. Jack and Willemstyn could probably not have been carried out except for the the interest and assistance given them by Mr. Jas. A. Farrell, president of the United States Steel Corporation, and by the officials of the American Bridge Company.

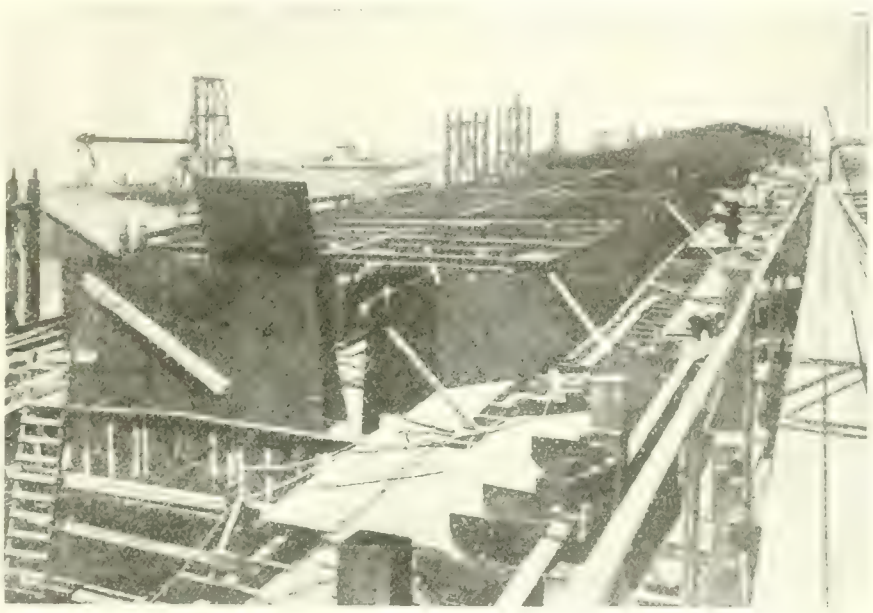

FIG. 1. VIEW OF A FABRICATED SHIP IN COURSE OF CONSTRUCTION.

### Scope of System

The construction of fabricated ships makes it possible to have the steelwork done by those who are specialists in the line of fabricating steel with all of the special tools and labor-saving devices at their disposal. It relieves the mind of the shipyard operator from the multitude of detail that goes with such work, reducing his problems to those of engineering, erection, riveting and assembling by the workmen, and to installation of other units of outfit and equipment.

The type of ship which the Chester Shipbuilding Company has built, and which it and the Merchant Shipbuilding Corporation are now building, provides for the use in all places of conventional ship shapes and ship plates, subject to the rules, inspection and survey of the registration society, both as to quality and material, dimensions, riveting and other matters. These vessels are cargo carriers of about 8,800 tons to 9,000 tons deadweight capacity with poop, topgallant forecastle and bridge, the latter being about 124 ft. long. The decks, with the exception of the poop and topgallant forecastle, are without sheer at the centre line. Complete double bottom for carrying of fuel oil or water ballast is fitted. The machinery is located amidships and consists of high and low-pressure turbines driving a single screw through reduction gears.

In the emergency which has recently arisen there have been proposed ships constructed from bridge shapes and universal mill plates with regard to which the writer has no personal detailed knowledge. It would appear to him that there might arise certain difficulties in using this character of material in the construction of ships, but he would prefer to leave to those who are personally cognizant of the matter any questions in regard to this.

### Tanker Developments

During the late winter of 1912 there was a sudden demand for oil tankers, while freight charters were low and cargo ships plentiful, and almost anything which could be made into an oil tanker was used. Mr. Jack then conceived the idea of using a system of vertical cylindrical tanks which were to be built and tested ashore, then installed bodily in the steamer. Two cantilever-type colliers, the Borgestad and Fritzoe, were acquired under long-term charter. Contracts with Pittsburg tank builders and New York pipe fitters and shipwrights were entered into. The tank builders started to erect the steel (amounting to about 900 tons) long before the arrival of the steamer, and by June the loading of the tested tanks in the Borgestad was begun, and the actual loading was finished in 10 days. It is needless to say that almost unsurmountable difficulties had to be overcome—in the first place, on account of the use of cylindrical tanks for ships; secondly, because of the manufacture of these tanks by tank-builders, the riveting by house-smiths and several other "objectionable" features which were not done according to old-time custom. Mr. Jack, during this time, spent several months in Norway to adjust matters with the classification society and had to withdraw the second ship from their class and change to Lloyds. The first ship sailed in September, 1913, without class, which was only again assigned after a trial of three months.

During 1913 the Escalona, then building at a British yard, was changed into a

*A paper presented before the Society of Naval Architects and Marine Engineers, at New York, November, 1917.

**Member of Council.

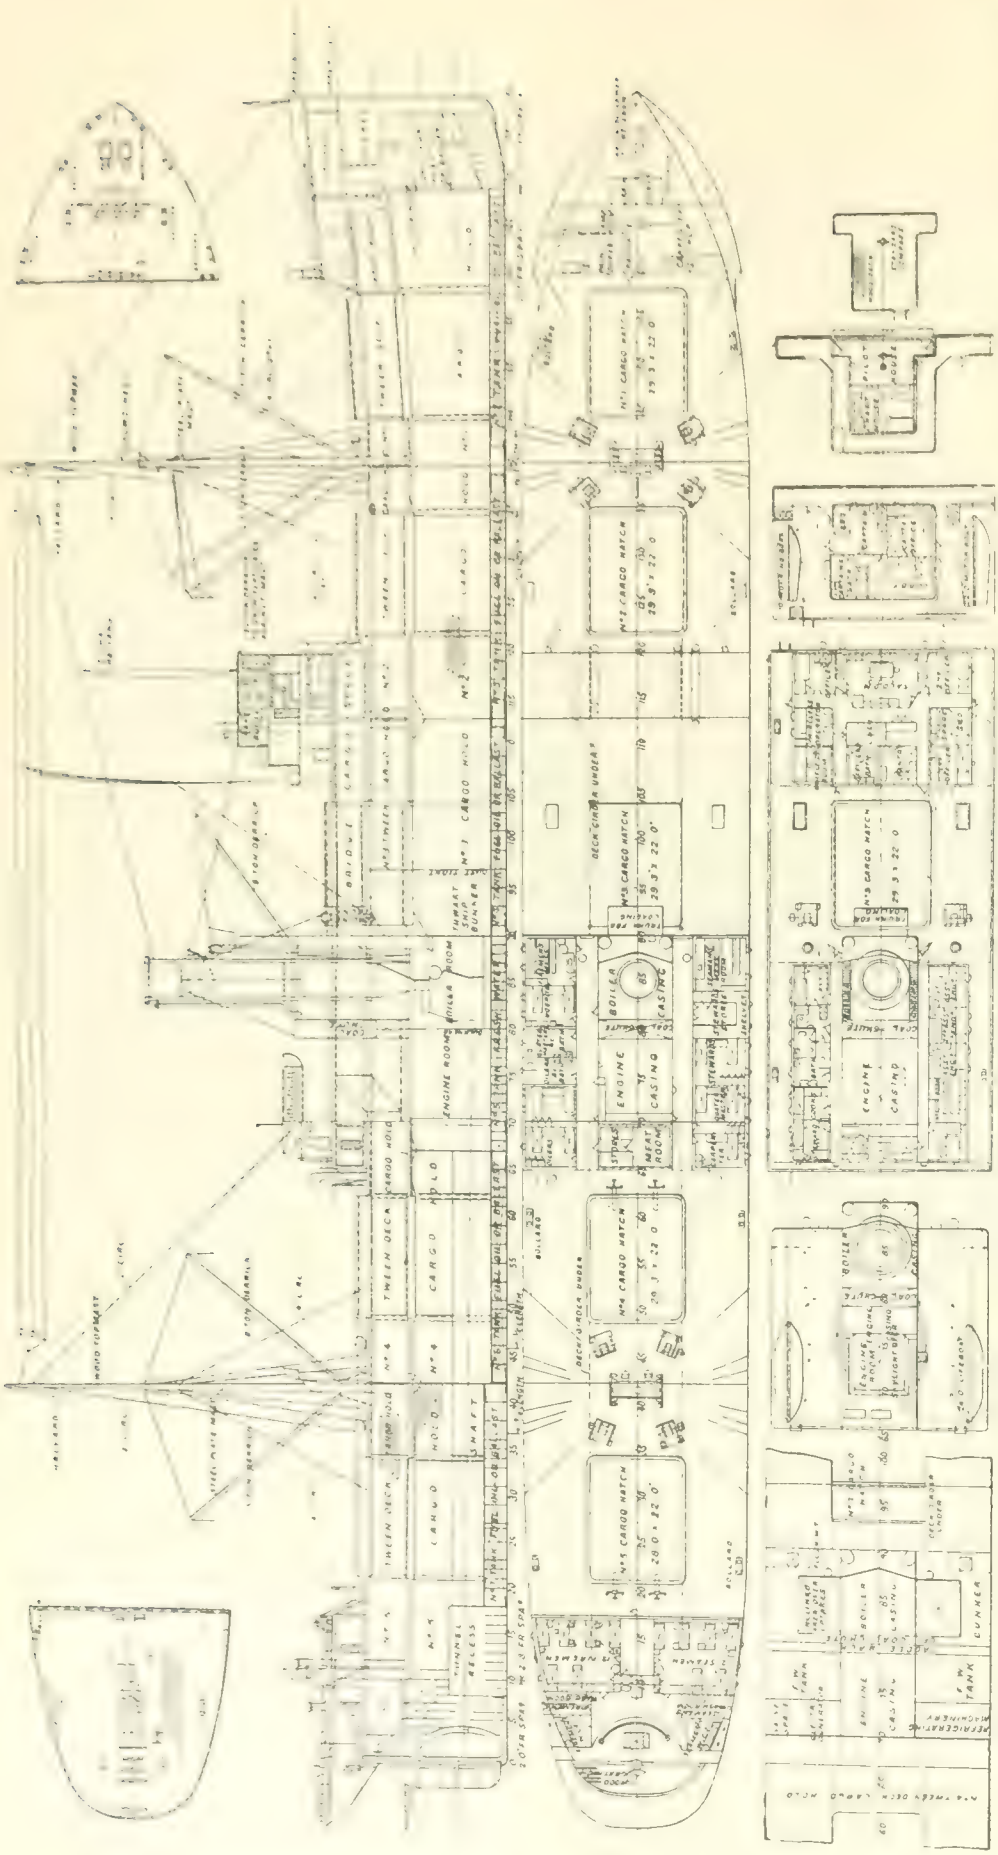

FIG. 2.—LONGITUDINAL SECTION AND DECK PLANS OF FABRICATED SHIP.

cylindrical tanker, but, due again to difficulties of classification, horizontal tanks were installed. These tanks were also manufactured and tested complete outside the shipyard. In the fall of that year three ships were started in Great Britain on the general design of the tankers now building at Chester, but the shipyard would extend the fabricating portion only to the cylindrical tanks.

In 1914 the Chris Knudsen and the Mills were converted on this side. The former was on the type of the Borgestad. A new departure was made with the Mills. The tanks in this ship were connected to tanktop and deck, a trunk built on deck and connections made from tank to tank and to the ship's side, thus forming cylindrical tanks and spaces between tanks and shell, with oiltight centre line bulkhead between tanks. Practically all the material was ready for assembly when shipped from Pittsburg. All holes were punched and countersunk, and stiffeners riveted to trunk sides, centre line, &c., wherever possible before shipping. The only pieces which were left blank were the outstanding leg of bounding angles connecting to the old ship's structure, and one edge of the transverse bulkheads. On account of the peculiar dome roof construction of tanks, which dome formed into rectangular trunk, only about 60 per cent. of the material was multiple-punched and the balance single-punched. The ships converted at New York were all erected with regular tank builders' outfits, consisting of a gantry or stiffleg derrick, air compressor outfit, blacksmith's forge and one or two ships' fitters. All piping, ventilating, &c., was fabricated beforehand, except the closing pieces.

### Initial Efforts

The above experience is given in some detail as it was gradually leading toward the fabricated ship, but in taking up the fabricated ship as a whole another difficulty arose on account of the size of the job involved in fabricating complete ships, involving thousands of tons of steel instead of hundreds. The tank manufacturers previously engaged could not entertain the proposition, and others were quoting prices which made the undertaking impossible commercially. The American Bridge Company, however, after several months of search and discussion, decided to fabricate two ships, but would only undertake to do the absolutely parallel midship body. About 60 per cent. of the total steel weight of the first two ships was thus manufactured. This was increased to 70 per cent. on the following ships, and to-day the bridge shops contracted for 85 per cent. of the hull steel and will fabricate also part of the curved portion of the ship. Of course a 100 per cent. fabricated ship is possible, but with the present bridge-shop equipment this is not obtainable. They will first have to increase their furnace facilities to take care of the bending of frames and the

beveling of angles, which may be done in the near future if the standard ship is here to stay.

### Duplication Necessary

The manufactured ship is a commercial possibility only if duplicate ships are built and, therefore, this policy was adhered to as far as possible from the beginning in contracting for the ships at Chester, there being but four different classes. These classes are as follows:—

1. Tank ship of about 9,000 tons deadweight capacity, fitted with cylindrical tanks on Jack's system. The vessel is built with topgallant forecastle, poop and short bridge. The main deck at centre line and top of expansion trunk are without sheer. Cylindrical tanks extend from tank top to under side of main deck, and a continuous trunk extending between poop and topgallant forecastle takes care of expansion and provides a working deck between the bridge, poop and forecastle decks. Machinery is located aft and consists of a high and low-pressure turbine driving a single screw through reduction gears.

2. Two-decked freighter to about 8,800 tons to 9,000 tons deadweight capacity, having poop, topgallant forecastle and bridge, the latter being about 124 ft. in length. This vessel is built with sheer. Complete double bottom for the carrying of fuel oil or water ballast is fitted. Machinery is located amidships and consists of high and low-pressure turbines driving a single screw through reduction gears.

3. Shelter-deck freighter of about 9,300 tons deadweight capacity, having poop, topgallant forecastle and bridge. Complete double bottom for the carrying of fuel oil and water ballast is fitted. Machinery is located amidships and consists of high and low-pressure turbines driving a single screw through reduction gears.

4. Two-decked freighter of about 8,800 tons to 9,000 tons deadweight capacity, having poop, topgallant forecastle and bridge. The decks, with the exception of the poop and forecastle decks, are without sheer at the centre line. Complete double bottom for the carrying of fuel oil or water ballast is fitted. Machinery is located amidships and consists of high and low-pressure turbines, driving a single screw through reduction gears.

### Riveting Details

Except as to details, which may be modified to provide ease of fabrication, the fabricated ship does not differ essentially in structure from any ship of a similar class. One of the prime questions involved is that of multiple punching. The greatest difficulty with the arrangement for multiple punching lies in the fact that the minimum distance from centre to centre of punch dies in a multiple punch is regularly 2 in., which distances can occasionally be reduced to 1⅞ in. The term "multiple punch" implies that the spacing of rivets is to be laid out so that the spacings of rivets in different successive rows are in multiples of each other or in multiples of 2 in. Take, for example, a butt spacing of four diameters of ⅞-in. rivets, equal to 3½ in. The frame riveting in this case could be six diameters, or 5¼ ins., which is no multiple of 3½ in., and neither is 3½ in. a multiple of 2 in. A compromise is made in this case by making an average butt spacing of 3½ in., which can be done by spacing in groups of three, viz., 3¼ in., 4 in., 3¼ in. The punches for the butt and frame spacing would be spaced in the machine as follows: 3¼ in., 2 in., 2 in., 3¼ in. The first, second, fourth and fifth punches would be used for the butt spacing. The first, third and fifth for the frame spacing, allowing for a 5¼ in. spacing. Where the butt spacing is 3½ diameters and the frame spacing 7 diameters, such as on smaller size ships, there is not much trouble, but the multiple punch is hardest to apply on the 9,000-ton, clear-hold, single deck ships, with their 5½ and 6 diameters frame riveting. Again, on the larger ships, with 4-in. butt spacing it is easier to be according to rule, and it should be here noted that Lloyd's Register of Shipping has been very progessive and broadminded in allowing the use of the average spacing instead of the strict and absolute adherence to stated rules.

The first thing to do on a ship designed for multiple punch is to arrange the midship section in such a way that all longitudinal rows of holes fall in line with the principles just explained; second, to arrange the plate width so that the greatest number of equal width plates are obtained; third, to see that if possible each plate is symmetrical about the long centre line of the plate, so as to avoid any possible countersinking errors. No templates are required for setting the multiple punch, which is entirely done from the typical rivet spacing drawing.

### Human Element

In staggered riveting, the minimum longitudinal spacing between the rivets of one row and those of the other is 1 in., but 1⅛ in. is preferable. This space is required for the stops and pawls, which stop the table during the downward stroke of the punch-head. It is, of course, possible to reduce the minimum space to small fractions, but then the human element of error is introduced, as a man has to insert a liner between stop and pawl, equal in thickness to the change in spacing wanted. Otherwise the machine is electrically controlled, except the throwing in of the clutch for punching.

A "pole," being a batten about 3 in. wide by ½ in. thick, and of such length as required, is used as template for the longitudinal spacing. Steel stops are inserted in the holes of the batten corresponding with rivet spacing, or, on the newest machines, steel stops are set up in a steel rack to suit the pole. Different color of light is shown where butts, edge-seams, frames &c., occur and the man on the levers is acting solely according to these colors

The multiple punches have, as a rule, only three or four set-ups, that is to say, one set-up for butts, one for edge-laps, one for frames, one for, say, intercostal angles in conjunction with the edge-laps. In this case the watertight bulkheads could not be punched if the holes would not entirely coincide with one of the four set-ups? It is possible to omit a few holes in some of the set-ups, but this is done only by hand. The man on the punch can release any number of punches temporarily by disconnecting the gag-operating gear for these punch dies.

The Chester Shipbuilding Co., Ltd., has, wherever possible, carried out the idea of duplication and standardisation, but very often has had to abandon it in detail. The hull, engines, boilers, and in fact all large items for a group of ships have been duplicated. The dimensions for all but two ships contracted for by the Chester Shipbuilding Co. are: length, 401 ft.; moulded breadth, 54 ft.; moulded [illegible] sheer, but in the latest type sheer is dispensed with and a raking forcastle and poop substituted, giving the effect of sheer but simplifying the work of manufacture. The results of the fabrication in the Bridge Co's mills as outlined above is beyond criticism. Work is fair rivet holes require no reaming, and the resulting fit of joints and water tightness is excellent. Constructing a ship becomes to a great extent a problem of routing, handling and erection of material and riveting.

The Chester Shipbuilding Co. and the Merchant Shipbuilding Corporation are now building some 68 ships on the manufacturing principles outlined above. It is expected to embody even more than has been possible in the past the manufacturing idea, [illegible] of labor shortage, to do a maximum of skilled shipyard labor of the conventional kind.

## BRITISH COLUMBIA SHIPBUILDING

EVERY shipyard in British Columbia engaged in constructing wooden steamers for the Imperial Munitions Board is well ahead of its schedule, according to E. C. Walsh, who is the official responsible for the lumber going into the vessels, and whose department is one of the most important under the Munitions Board. The building of these twenty-seven steamers has meant a great deal for the lumbering industry of the province, for about 1,400,000 feet of timber is needed for each ship, and ten million feet has yet to be delivered. Not only are old-established logging camps engaged on getting out ship timber, but four new camps have been started for this purpose. Merrill & King, on Thurlow Island, get out 100,000 feet a day, and a similar quantity is logged on Thurlow Island at the P. D. Anderson camp. The Hansen camp at Granite Bay is get-

[illegible] feet, and so does the Jackson Bay camp, which is a Munitions Board plant operated by the Colonial Fruit Co. The result of the dispatcher has resulted in lumbermen getting out the long lengths necessary for the programme, and the production of ship knees is also a big feature. These knees are very essential in order to give the requisite strength to the vessels, and the fleet now under construction will be a big advertisement for British Columbia timber.

### Lumber Inspected

The lumber is very carefully inspected and it must come up to a grading set by Mr. Walsh, who was with the Hastings mill for twenty-five years. The Inspectors' Bureau Association also checks up the quality and issues a certificate if it comes up to grade, and there is a representative at every mill cutting timber for the ships. The shipyards are also held responsible for what they receive, so there is small chance of faulty lumber [illegible] the vessels.

At the Western Canada Shipyards, of which W. W. Clark is superintendent, there are four ways. Number One hull is completed and should be launched at any time, but she was finished so far ahead of the scheduled time, that the shafting and other engine room gear has not arrived. Otherwise she could be sent into the water. When it is considered that the ground for the yard was broken as recently as June 5, it will be seen that rapid work has been done. Work on the second vessel will be about 20 per cent. faster than on the first ship as the workmen get more efficient and more men are trained. The ceiling has been started on the third vessel, and the fourth is in frame, while the saws are whining on the lumber for the fifth.

False Creek is beginning to look like a miniature Clyde, for right across from the Western Canada yard is the big Coughlan plant, where steel steamers are under construction and the hull of one is looming large, for she will be launched this month.

### Launching Dates

The launching dates set for the six ships at the Western Canada yard are: Feb. 1, March 15, April 21, May 15, June 7, and June 13. The dates at Lyall's yard, North Vancouver, are: Jan. 20, Feb. 10, March 2, March 23 and April 11. The Cameron-Genoa, Victoria, launching dates are: Feb. 1, March 1, April 1 and May 1. The Foundation yard, Victoria, dates are: Jan. 20, Feb. 20, March 20 and May 20. The dates for the New Westminster Construction and Engineering Co. are: Feb. 1, March 1, May 15 and June 15, and for the Pacific Construction Co., Coquitlam, March 1 and May 1.

All the yards engaged in the work have been fortunate in that no labor troubles have interfered with the progress, and Mr. Walsh states that the greatest harmony has prevailed, all hands apparently realizing the need for turning out the tonnage as rapidly as possible. This feeling is prevalent from the logger who drops the trees to the men who build the ship, and the six yards are working in a spirit of friendly rivalry.

The steamers under construction are 250 feet long, 43½ feet beam, and a moulded depth of 25 feet. They will carry 2,800 tons deadweight on a draught of 21 feet, and most of the lumber used in construction is Douglas fir.

### Are Strong Vessels

A visit to the Western Canada yard shows that the specifications of the Imperial Munitions Board are high. From the vessel in frame to the completed No. 1 hull every timber seems to be of beautiful lumber of immense strength, and the vessels are very solidly built. There is no evidence of any weakness, and the magnificent timbers are a great testimony to British Columbia's great lumbering asset. The ships are to be built to Lloyd's A1 classification and the British Board of Trade's requirements for cargo steamers.

The frames, of course, vary in size. Some are as big as 21 x 23 inches, and the smallest is 12 x 14 inches. The rudder-post is 37 feet long and 20 x 20 inches, and is in one piece, as is the propeller post, which is 30 x 36 inches and 37 feet long. The beams are 14 x 12 and 14 x 13, and the stem is in one piece, 45 feet long and 18 x 26 inches.

## UNFOLDING ROMANCE OF THE AIRPLANE

By Frank H. Russell*

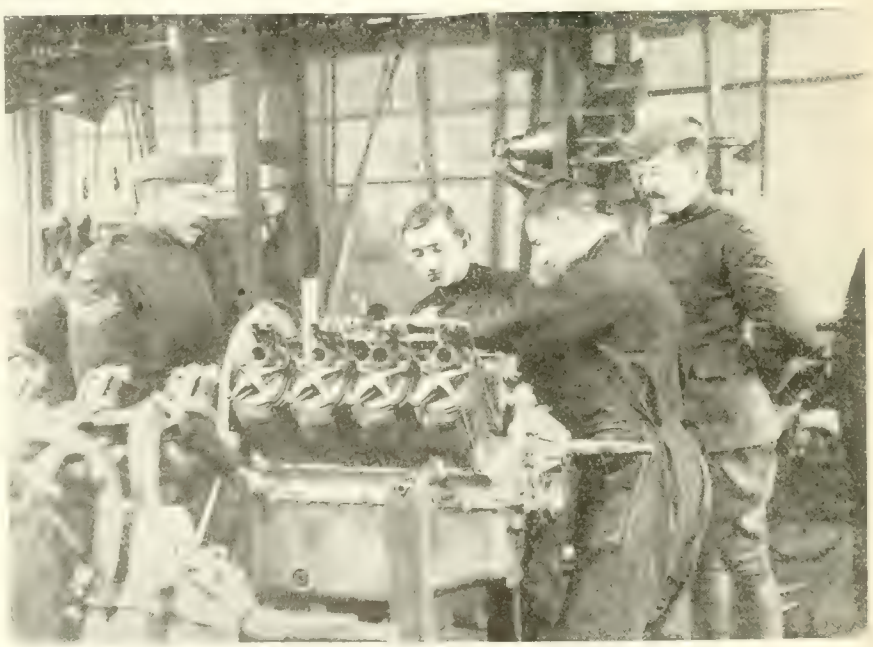
THE romance of oil and of steel, of the railroads and of the motor car, has been written, though the stories are of such recent origin that the pioneers in these enterprises are still among us, masters now of the forces that they created. But their stories, fresh as they are, yet are old, and to-day a new tale of success is in the making. It is the romance of the air and of the infant industry, already grown to manhood's figure, which has revolutionized warfare and is waiting only the coming of peace equally to make its impress on the normal life of the world.

It is less than a score of years ago that the first heavier-than-air machine successfully carried a passenger into the air. It is less than fifteen years ago that the art of controlling such a craft was imparted by the inventor to another, yet to-day air-craft have been standardized, and factories turn them out with the case that motor car builders produce their product. Throughout the world aviation schools are in operation, and thousands of students are acquiring the art of flying just as their fathers studied and mastered the control of the motor car.

Any figures which aspire to consider the whole of the civilized world must be approximate at best, and possibly far from accurate, but it is safe to say that to-day upward of a billion dollars is invested in an industry which within the memory of the present generation was capitalized solely by the private fortunes of the brothers Wright.

That capital will be doubled, trebled, perhaps, before world peace succeeds the present struggle, and it is no impossible conception to picture the airplane industry at the end of the war as the greatest industry ever created by man; an industry employing more capital, consuming the energies of more men, and rendering the greatest proportionate service to mankind ever attained by any other form

*President Manufacturers' Aircraft Association.



INSTRUCTING BRITISH RECRUIT MECHANICS IN THE WORKING OF A 70 HORSE-POWER RENAULT MOTOR

Passed by Official Press Bureau

of human endeavor. For war is not the only field in which the airplane may prove its worth. It is in the ways of peace that its greatest potentialities will be realized, although it seems to have needed the present world conflict to win recognition for even the least of its merits.

### Pioneers' Resources Low

It is no secret within the industry, and it must have been widely suspected without, that the men who had the vision to foresee the future of the aircraft when the Wright brothers gave it to the world and who had devoted themselves to the task of developing a demonstrated principle into practical manufacture, had come close to the end of their resources when the world conflict gave aviation the impetus which to-day has launched it as an industry past the experimental stage and well into the production period.

As an industry the existing manufacturing plants and facilities practically did not exist up to three years ago, or at the outset of the world war. From the time of Darius Green and his flying machine, Professor Langley, and the brothers Wright, there had always been men with the vision and the determination to develop the aircraft into a practical utility. But they had been tremendously in the minority among their fellow-men. The pioneers in the industry developed their ideas against the dominating negative thought of practically the whole world. They were regarded as interesting visionaries, and it is needless to say that among them were no geniuses of finance; the art of flying was not one to attract bankers. Here and there in the United States shops had been erected that were little more than shacks, and in them enthusiasts tried with small skill and less money to develop the ideas they had conceived.

Progress was necessarily slow, and the attitude of the public was well illustrated in the newspapers, which showed a tendency to print a paragraph about a successful flight and a column about a mortal accident. There were accidents, of course. In the sixteen years up to 1916 the loss of life, time and money in the effort to make the airplane a commercial proposition was appalling.

But as is always the case with a new venture, if it be of an exciting, thrilling type, there was no lack of men willing to fly. Any man who could put together a machine could find some daredevil to try to fly it. Finding money was not so easy; men who had entered the game enthusiastically at the outset soon sunk their own fortunes in their experiments and then sought for financial backing among heir friends. What they received was generally small in amount and grudgingly given. The public had not their ability to visualize the future and the Government seemed even more blind to the possibilities of aviation.

### War Its Salvation

It was a sport, at best, was the chief argument against investment. It has no utilitarian purpose, and no market for the aircraft could ever be established beyond the ranks of wealthy young sportsmen who were willing to pay well for the notoriety and the sensations of an aviator. That was the average attitude of the man with money, and to offset it the pioneer builders could advance only predictions that a commercial future was in store for the airplane as a means of transportation for persons, freight and mail; that the aircraft made possible journeys beyond the scope of ships and trains, and that it practically eliminated distances by the speed of its progress.

Such arguments, it need scarcely be said, were seldom effective and the development of the aircraft languished for lack of financial support. But here and there engineers were turning their attention to the possibilities offered by the new art and here and there practical builders were experimenting in small ways with airplane motors, striving to adapt existing automobile motors to the needs of an airplane. They met with a measure of success and, as early as 1907, practical machines that actually flew were turned out by more than one maker in this country. But up to 1914, when the airplane industry may be said actually to have come into existence, conditions were little changed. There was little demand for aircraft and no monetary incentive to build them.

AMERICAN AEROPLANE ENGINE ON TESTING BENCH READY FOR TRIAL. THE OPERATOR IS PROTECTED AGAINST INJURY FROM THE PROPELLER BY HEAVY WIRE SCREEN

Passed by Committee on Public Information

Then came the war, and with it an ever-increasing demand for airplanes and pilots, until to-day the United States has appropriated some $720,000,000 for the construction and equipment of aerial fleets for the army and the navy and is committed to a program that contemplates the construction of 22,500 airplanes this year, with a doubled output for 1918, the training of hundreds of thousands of aviators and the creation of a new branch of war service that shall assail Germany from the skies and wing a way to victory that has been denied to the older branches of the service, the army and the navy.

### Great Britain's Output

To-day some $40,000,000 is invested here in the airplane industry. Approximately 15,000 men are employed in it, and the combined output of the country is about 200 planes a week. Factories devoted exclusively to the construction of airplanes and their parts cover a floor space of more than 4,000,000 square feet, and some twenty-five manufacturers are now making report to the Automotive Committee of the Council of National Defense on their capacity, their capital-

capacity.

These figures give some notion of the [illegible] experiences of Great Britain in the aviation field indicate that these are but the preliminary steps in the march of progress which the United States is yet to make.

Great Britain, for instance, has $375,000,000 invested in her airplane industry and [illegible] facture 41,000 planes a year. The total appropriation by the British Government for airplane work this year was $600,000,000. The proportion of capital invested here to that invested in Great Britain is about 1 to 9¼, yet the present capacity of the United States is approximately one-quarter that of Great Britain, and it is planned to double this output by the operation of night shifts of labor.

It has been found that there are about 4,000 hours of work in a finished airplane, so it is generally estimated that it takes eighty men, working a fifty-hour week, to produce one airplane. It is not likely that this relation will be altered much, for the same proportion has been found to hold true in England, but output can be increased, not only by the employment of additional shifts, but also by the utilization of the facilities of allied industries.

Ordinarily a construction program such as the United States has authorized would require at least a year of preparation in any industry, but time is life and blood now and the gap between the experimental stage of before the war and the present quantity production of airplanes is already partly bridged and [illegible] be completely spanned within six months.

The automobile industry is at hand with its tremendous organized facilities for quantity production, and on these plants the airplane makers will depend in some measure for the construction of motors. The bodymaking departments of these automobile plants may be used for the fabrication of fuselage and wing frames under the direction of airplane experts, and thus all the present sources of supply will be maintained and strengthened.

There is another important factor in the situation, however. This is the matter of cross licensing, which has been largely misunderstood by the public, but which is to play a most important part in the successful fulfillment of the Government's plans. By it the differences which have existed among makers almost since the Wrights obtained their first patents have been amicably settled, and any manufacturer worthy of the boon may now avail himself of all the patents relating to the aircraft industry.

*The Analist.*

VIEW IN BRITISH REPAIR SHOP WHERE ENGINES ARE OVERHAULED AND PUT IN SHAPE AGAIN

Passed by Official Press Bureau

## U.S. AIRPLANE MOTORS

IT is reported from Washington that experts under the aircraft production board are already at work upon an engine that is expected to surpass the Liberty motor in power, while retaining all the qualities for quantity production.

While the original Liberty motor included no mechanical innovations, or experiments, the designers have been given full latitude in the new machine and it probably will mark distinct progress in the art of airplane engine designing. For that reason details of construction are highly confidential.

American experts have worked on the theory that a good big airplane is better than a good little aeroplane. They believe super-dreadnoughts of the air will be the masters of the air and consequently the new engines are being developed to run planes of increased size and fighting power. Months ago General Pershing urged that American designers anticipate craft armed with six machine guns each, three heavy and three light. At that time no serious attempt was being made in Europe to get more than four guns aboard any plane.

The Navy Department also is at work on designs for advanced types of seaplanes. For the present the capacity of the new plant at the Philadelphia yard, where nearly 1,000 men are employed, is needed to turn out the accepted type of flying boat, but some of its facilities soon will be diverted to development of enlarged and improved flying boats.

## CHROMIUM-STEEL FOR MAGNETS

OWING to the commandeering of tungsten for military purposes, German electricians found themselves without tungsten for their magnet steels early in the war, and experiments on the use of chromium in the place of tungsten, which had already been projected before the war, were accelerated. The research has been conducted in the Reichsanstalt on behalf of the Verband Deutscher Elektrotechniker. The preliminary report, published by the Reichsanstalt in 1917 did not give particulars, which were, however, to be communicated to members of the Verband on inquiry. Krupp's works supplied 37 specimens of steel containing varying percentages of chromium and of carbon; they had been turned into rods and hardened in various ways in the works, and were then aged, after the method of Strouhal and Barus, by repeated heating, cooling and mechanical stress, while being tested at intervals in the Reichsanstalt. The unfinished investigation concerns also the temperature co-efficient of magnetisation and the durability of the steels. It results that on an average chromium steels, which have undergone suitable heat treatment, do not rank below tungsten steels; the very best magnetic chromium steels, however, are not equal to tungsten steels. Technically, chromium steels would thus appear to be quite satisfactory, while for special researches their further improvement is desirable.

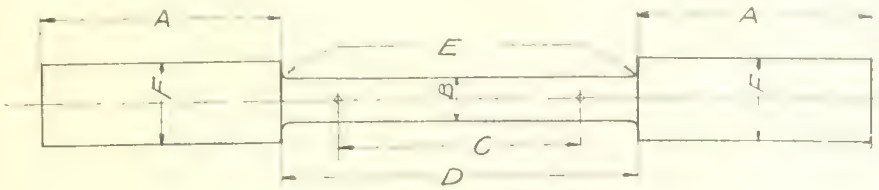
IN the old days when light grinding spindles and relatively light machines only were available, it was desirable to leave as little stock for grinding as possible to reduce the time required. With the modern internal grinding machine, however, this is not true and it is now considered wiser to leave a liberal amount of stock, as this reduces somewhat the accuracy required in chucking the pieces.

# Shell Inspection: What a Shell Inspector Should Know--I.

By Chief Examiner

*The prolongation of the war with the increasing importance attached to quantity and quality of ammunition make it more than ever essential that inspection, to fulfill its purpose, must be applied intelligently, however unremittingly. A little knowledge is sometimes dangerous if misapplied, and the author of this article endeavors to make clear the object of inspection, rational methods of carrying it out in practice, and incidentally the disastrous results attending ignorance or carelessness in performing the duties attached thereto.*

WHETHER he be shop inspector or government man, anyone who is responsible for the inspection of shells—high explosive or shrapnel—should understand the entire manufacture of them, from the pouring of the ingot to the shipping of the finished article. The subject is intensely interesting to those who realize the responsibilities attached to the work, but



HIGH EXPOSIVE SHELL TEST BAR

those who handle it from a purely mercenary motive will probably find less interest in it than they do in their ordinary duties.

### The Material

The first thing to think about is the question, "what is steel?" The answer is simple and may be given in two words: iron and carbon. In other words iron with all its impurities removed. Some of these impurities are added later to give the steel the necessary elasticity required for shell making, but they can only be added in certain quantities.

Manganese makes the steel crumble or break up; phosphorus and sulphur are undesirable in steel for shell making, as they render it very brittle. Phosphorus is especially dangerous, and a large amount of it makes the steel unworkable. An excess of sulphur prevents proper forging when in billet form. The percentage of these substances allowed by the Imperial governmen are: carbon, maximum .55 per cent; silicon, maximum, .35 per cent.; manganese, maximum, 1.0 per cent., minimum, .4 per cent; phosphorus and sulphur, maximum, .05 per cent.

Now comes the interesting process of manufacturing the steel. This question has of course been discussed and explained in detail often enough, and this account is only given as a rudimentary explanation, merely for the use of those interested in shell inspection.

Iron first comes from the ground in the form of ore. This ore must then be refined—that is, all its impurities must be taken away. There are several processes by which this is done, and the first step in each process is the blast furnace. The iron ore is charged into a tall stack and with it a quantity of coke and lime which act as fuel and flux respectively. The fire is started and the whole mass, aided by a strong blast of air, becomes hotter and hotter till the iron is simply fused out of the ore and becomes white hot liquid. This liquid is then run off into channels made for the purpose on the floor of the cast house and is then known as pig iron.

### From Pig to Steel

Now pig or cast iron is hard, but it is not tough, or elastic, and is therefore not suitable for making shells. It is too brittle owing to the fact that its impurities have not yet been removed. It is not malleable or workable. The proper quantities of carbon, silicon, and manganese have to be obtained to make it workable, but the iron must first be refined in order to remove certain excess impurities as well as to permit such additions of others as are necessary to meet specifications.

This purifying is carried out in Canada chiefly in what is known as the basic open hearth furnace. The pig iron is again brought to a white heat in a special type of furnace by means of hot air and gas, so that the remaining impurities are reduced to the desired limits through absorption into a slag formed of molten limestone. While still molten, the final proportioning quantities of carbon and manganese are added. This fiery liquid is then poured into a big ladle from which it is drawn off or teemed into moulds. It is drawn off from the bottom so that all the slag and dirt may be left in the ladle and not get into the moulds.

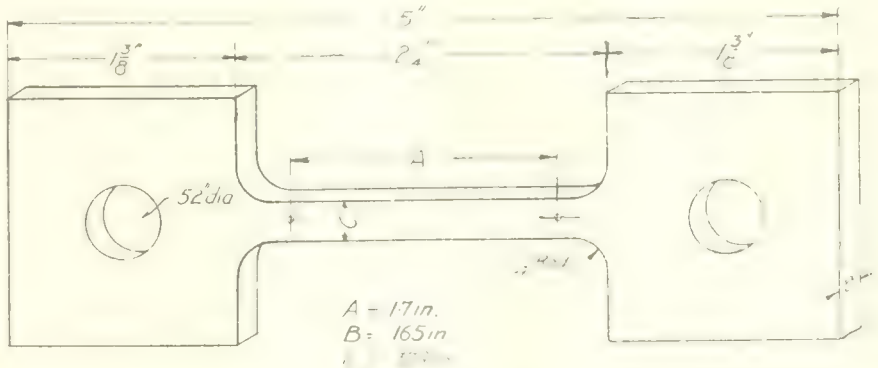
Another process is the Bessemer, so called on account of the name of the inventor. In this case the iron passes direct from the blast furnace into a converter. A blast of cold air is blown through the bottom, and this, instead of, as would be supposed by the uninitiated—lowering the temperature—actually raises it, and the impurities are oxidized, passing off as combustible gases, and when the flame dies down it is known that they are all gone.

A third process is the electric furnace. The "juice" passes through the pig and scrap, which are put in together, in this case and brings the mass to a very high temperature, when a similar action takes place.

### Ingots and Their Defects

When the molten mass is poured into the moulds, it is known as an ingot, and defects begin to occur from that moment. Now we have to ask ourselves "what physical change takes place when the ingot cools?" The answer is simple—it contracts. This contraction first takes place from the outside towards the centre.

As the ingot slowly cools and contracts in this direction a cylinder of



SHRAPNEL SHELL TEST BAR

liquid metal. Then the contraction commences to take place from the centre towards the place where the first contraction ceased. This contraction outwards leaves small spaces in the centre [illegible] of the ingot, which are called piping. Of course the hot metal, in almost liquid form, at once fills up these spaces, but sometimes it does not entirely fill them up, consequently a small pipe is left when the ingot is cold. This is a serious flaw in the steel.

A portion of the ingot is broken off after being partly cut through, in order to discover this piping if possible. If piping shows, another cut is taken, and [illegible] still shows the ingot is scrapped.

After the ingot is poured it is rolled, while still hot, so that the diameter is lessened and the length increased. Sometimes, owing to dirt, a "crack" or "seam" develops, and when it does the ingot is useless because this type of crack will never amalgamate or join with the rest of the metal. Sometimes air gets in and causes bubbles or blow holes, giving the metal a spongy form called porosity—porousness. The ingot receives three rollings.

After the first rolling it is called the bloom, after the second, the bar, and after the third the sub-bar. The sub-bar is then cut into lengths and each length is called the billet. A billet is that quantity of steel required to make one shell. Generally no defects arise in the operations between ingot and billet, although they may and do develop in the rolling.

### Causes of Defects

There are six defects to be found either at the ingot stage or the forging which is the next operation. These faults are piping; cracks or seams, from contraction; cracks from slag or dirt; porosity, cones in the base, and eccentric forgings. The last one is of course found after the billet has been forged. Piping has been dealt with. Cracks from contraction are found when the contraction is not uniform as for instance when a current of cold air strikes the hote metal, or the forging rolls through very cold water. Cracks from slag or dirt explain themselves. Porosity has also been dealt with.

Cracks from contraction are also generally caused by the steel being burned. This weakens it when cooling and the pressure of any dirt or slag, or even air, causes the steel to develop them, and they sometimes show, when machined, as "rokes," "hair lines," and "ghost lines." The last two are also caused by the presence of sulphur, but the last is one of the mysteries in the manufacture of steel, and the exact cause has never yet been absolutely and definitely determined. This question will be mentioned again later. Ghost lines are so termed on account of their peculiarity of appearing and disappearing. If one is discovered after the shell has been machined it can often be filed out, but if the shell is left standing for 24 or 48 hours it will again show itself as bad as ever. The oxygen in the air seems to bring it out again, as also does the heat of the varnish-baking oven.

### Forging

When being forged the billet is heated slowly to approximately 2,100 degs. F. when it is forged. This is done by means of a punch, which descends at high pressure into the putty-like hot metal, and forces it up between the punch and the walls of a die of suitable size.

Cone defect.—If the billet is not heated equally right through there is a portion in the very centre which is colder than the rest of the metal. This colder portion, which may be very small like a pin head or as large, or even larger, than an ordinary marble is forced by the punch into the base end, and when the forging cools off, it is possible to knock the piece right out with a hammer. Very often this cone is not discovered till the base is machined, and even then it may not be discovered as it may not come to the machined surface of the steel. This is one of the most dangerous defects, and an inspector should make a practice, at the preliminary bench, of testing frequent batches of each heat by striking the hogged out base recess a sharp blow with an ordinary machinist's hammer, taking care, of course, not to mark up the recess with the edge of the hammer.

### Steel Requirements

Steel for shell making must be elastic. When the shell is fired from the gun it gets a blow of about 200 tons on the base. The rear half of the shell tends to overtake the front half, and there is a momentary bulging of the walls. The steel, if elastic, will immediately return to its original position. If it did not the shell would jamb in the gun and either burst the gun or fetch it back over on to its own men. The same result would happen if a shell were allowed to go through having cracks or seams. These would open under the pressure, i.e., chamber pressure, and would remain open. Ghost lines, hair lines and slag or sand holes are other dangerous defects which might cause the same thing and needless to remark must be carefully and continually watched for during the visual examination at both preliminary and final inspection.

The markings, of which there are four, will be found on every forging. They are: 1. The code letter; 2. The heat number; 3. The forge maker's initial, and 4 the government acceptance stamp.

The first is stamped on to show what firm made the steel. The second is the shell's name and denotes the heat or batch of ingots that were poured at one time, the third is to show what firm made the billet into the forging, and the fourth is put on by the government inspector after he has passed the forging as being correct and serviceable for machining. Before doing so he must gauge the thickness of walls, thickness of base, length over all, examine it visually, and tap it to find by the ring if there are any cracks.

### Specified Tests

The acceptance stamp is not put on until word is received that the tensile test piece has passed. To ensure that the steel has the proper elasticity required for the purpose of making shells, the Imperial government requires that there shall be three tests made of a portion of the steel itself from each heat number. These test pieces are sent to a laboratory chosen by the Steel Inspection Department.

The tests are: 1 chemical analysis; 2 compression; 3 tensile. The first is taken from the ingot, and the second and third from the forging. In the first case a portion of the centre or core of the ingot is drilled out and analysed. The hole is also examined visually to detect piping. In the second case a piece is cut from the forging and is turned to form a circular button half an inch thick by half an inch in diameter. This is put under a hydraulic press and compressed to one half its length. If it cracks, breaks or shows any other defect the whole heat number, i.e., every forging in that particular heat, is rejected. In the third case, a piece is cut from the wall of the forging near the base end and is turned to form the test bar.

This test bar is about 6 or 7 inches long and is circular. It is turned down in the centre and two punch marks are placed on this portion. The dimensions are as follows: A about 2 in., but it is not important to have this exact; B, .564 in. dia. for 6 in. forgings, and .461 in. for 4.5 in. forgings. C denotes the punch marks, and the distance between them must be exactly 2.4 in; D is about 3 in.; E denotes ⅛ in. radii, and at F the diameter should be about ¾ in. The two ends are placed in jaws made for the purpose, and are pulled outwards. The dimensions are all carefully checked both before and after the pulling, and the strain is from 41 to 50 tons. The bar must stand 41 tons' strain before yielding, and must not break under 50 tons, nor yield too much.

The above test is for high explosive shell. Shrapnel also has a tensile test and is taken during machining immediately after the shell is nosed in. A piece is cut from the wall, just above the driving band recess.

The distance A between the punch marks is .556 in.; B the thickness of test piece is .125 in.; C, the breadth of the narrow or centre portion is 1-16 in.; and the two end pieces are about 1½ in. square. Holes are drilled in the ends for the purpose of holding the test piece when pulled. In this case the yield point is 36 tons per square inch; the breaking point is 56 tons, and the elongation or stretch must not be less than 8 per cent. of the distance between the punch marks.

# The Preventable Waste of Coal in the United States*

By David Moffat Myers**

*While asserting that the saving or waste of one-fourth of the coal consumption of any industrial plant depends entirely on the efficiency of the management, the author emphasizes the fact that this fraction of the consumption relates exclusively to the boiler plants and does not include the large economies possible in connection with its distribution and use.*

As a means of far-reaching economy the Government of the United States should at this time apply intelligent and direct-acting efforts to the conservation of fuel at the industrial plants which are responsible for its greatest consumption.

The mining and distribution of the coal have been placed under the supervision of the War Coal Board in order more nearly to meet the crying needs in these directions, to use the railroad facilities more efficiently so that the present car shortage may be minimized and to apportion the coal in quantity and to uses deemed most expedient.

While this organized effort to bring about efficiency in the production and distribution of coal is being made, no parallel measures have been adopted to bring about a normal and practical efficiency in its use. The hundreds of large plants which are consuming fuel wastefully, in many cases more wastefully and carelessly than ever before, are directly and needlessly causing a large fraction of the existing car shortage.

### Preventable Waste of Fuel

The preventable waste of fuel in the boiler furnace of one steel mill which I investigated amounted to 40,000 tons per year, which at $5 a ton would cost $200,000. This was a comparatively modern plant. The efficiency of boilers and furnaces in a 14-day test was 55 per cent. The load factor was unusually favorable to high efficiency and could readily be raised to 70 per cent or over. This is only one example, and there are many more extreme cases. In one hand-fired plant the evaporation was raised from 6 to 9 lb. in a few days of instruction and continuously kept close to this higher mark with the help of coal and water measurements which were inaugurated. The saving was due exclusively to instruction and consequent better operation.

The saving or waste of one-fourth of the coal consumption of any industrial plant depends entirely upon the efficiency of its operating management. Let me emphasize that this fraction of the consumption relates exclusively to the boiler plants, that is, the production of steam, and does not include the large economies possible in connection with its distribution and use.

For well-known reasons the boiler plant offers the more lucrative field for producing economies, and these with a minimum of alteration in physical equipment.

Under present conditions a plant which carelessly operates at an efficiency of 40 to 50 per cent. receives from the Government the same consideration in the delivery of coal as the one whose efficiency is 70 to 75 per cent. This obviously is unfair and wasteful.

The government hands over, say, 200,000 tons of coal a year to a plant owner, but asks for no accounting as regards its consumption, nor any questions as to the amount of steam it is made to produce.

There is no doubt that very important economies in the use of food have already been effected by educational campaigns. These economies are largely the result of educating the ultimate consumer. The requisite propaganda does not attempt to teach the intricacies of food chemistry or the complex action of the gastric juices.

TABLE I TOTAL COAL PRODUCTION BITUMINOUS, LIGNITE AND ANTHRACITE, YEAR 1915.

| | Net tons | |
|---|---|---|
| 1. Bituminous and lignite | 443,462,509 | 85.2 |
| 2. Anthracite | 76,906,431 | 14.8 |
| 3. Total | 520,368,940 | 100 |

The object of this paper is to open a discussion which, it is hoped, will ultimately lead to the formulation of definite fuel conservation recommendations, to forward these recommendations to the proper governmental authorities as an official communication of this society, and to offer to the Government the services of the society for the organization, furthering and, as far as possible, the execution of the plan which may as a consequence be adopted.

There are, I think, two plans of operation worthy of consideration. The one might be termed the autocraatic method. This would involve use of authority to compel coal consumers to execute such measures of economy as the proper authorities might prescribe for any given case, limits to be set as to expense to the user. Such limits might be in terms of a percentage of his present yearly coal bill. Alterations should be directed chiefly, as previously implied, to purely operating improvements. Many objections would probably be made by consumers against this plan, but once in effect the majority would no doubt realize its pecuniary advantage to themselves. But its tendency may be too strongly opposed to democratic principles.

The other plan would be largely an educational one, in which patriotism and efficiency would furnish the motive forces required. The teaching must be accomplished with the utmost simplicity and directness. Above all it must be in such form as to be readily comprehended and applied.

The requisite information must reach the owners and managers of industries, and there must be simple instruction sheets for the engineers and firemen. The vital importance of daily accurate records of coal and water must be taught and information given regarding practical appliances for automatic measurements of both.

Blank forms might be sent in advance to plant owners in order to be advised by them, first, whether they would be willing to co-operate with a governmental organization offering to assist them in reducing their coal consumption, and second, to obtain such data as to size, type, equipment, operation and fuel consumption of the plants as would enable a classification that would permit a government board of experts to send such instructions as would include the information needed for any one class of plants.

This work would be very greatly aided by a staff of experts ready to visit plants when so requested by owners, and make investigations and recommendations and keep in touch with the progress of economies. Included in such a staff must be men intimately familiar with practical operating economies, whose duties would be the delivering of lectures or talks which should be planned so as to reach directly not only managers and owners of the industries, but also the chief engineers and firemen of the boiler plants.

The United States Bureau of Mines has for a number of years engaged in obtaining and disseminating scientific information regarding the mining and consumpton of coal, and the results of the work have been of great value to technical engineers who are able to use and apply it.

Six hundred million tons of coal was mined in the United States last year. It is predicted that 700,000,000 tons will be mined this year, and next year's production will likely be still greater. Of this quantity approximately 67 per cent, or 469,000,000 tons, will be burned for steam-making purposes on land, assuming the same percentage consumption for steam production as existed in the year 1915.

The saving or wasting of one-quarter of these coal [illegible] over 117 million

*Presented at the annual meeting, December 1917, of the American Society of Mechanical Engineers, New York.

**Consulting Engineer, New York City.

tons, depends on the efficiency with which we operate our boiler furnaces. If we actually saved by proper methods only 50,000,000 tons per year, this economy would result in freeing for other important service the use of 1,000,000 fifty-ton freight cars per year. The significance of such an economy may be realized when it is stated that the number of cars thus released for other service would be equivalent to 15 per cent more than the combined yearly coal-carrying capacity of the Baltimore and Ohio and Southern Railway systems; approximately equal to that of the Pennsylvania R.R. system on lines east of Pittsburgh, or 1 2-3 times the number of coal cars hauled by the Norfolk & Western. The direct saving to our industries would be $250,000,000 worth of coal per year, if figured at $5 per ton.

This saving would be 50,000,000

469,000,000

10.65 per cent of the coal now burned for steam production. It is impossible to state the present average efficiency of boilers and furnaces, but I have personally spent sixteen years of concentrated study in the investigation and improvement of steam and fuel conditions in factory power plants, and I have never visited a plant of this class where a saving in coal of at least 10 to 12 per cent could not easily be made. The poorer the conditions found the easier it is to make an attractive saving in fuel.

TABLE II PERCENTAGE DISTRIBUTION OF BITUMINOUS COAL AND LIGNITE PRODUCED IN THE UNITED STATES AND IMPORTED IN 1915, BY USERS

| | % |
|---|---|
| 1 Railroad fuel | 28.0 |
| 2 Steamship bunker fuel, tidewater | 2.0 |
| 3. Steamship bunker fuel, Great Lakes | 0.3 |
| 4 Manufacture of beehive coke | 9.3 |
| 5. Manufacture of by-product coke | 4.3 |
| 6 Manufacture of coal gas | 1.0 |
| 7 Domestic and small steam trade | 16.0 |
| 8. Industrial steam trade | 33.0 |
| 9 Export fuel | 4.0 |
| 10. Steam and heat at mines | 2.0 |
| 11 Special uses | 0.1 |
| 12. Total bituminous and lignite | 100.0 |

NOTE.—Imports were only a little over one-tenth of one per cent. and are, therefore, neglected.

No information is available for complete classification of the distribution of the anthracite, but it is estimated in report on "Coal in 1915*" from which Tables I. and II. are made, that 50,000,000 net tons of anthracite were used in 1915 for "heating households, apartment houses, hotels, and office, school and other buildings." This leaves about 27,000,000 net tons or 35 per cent. for industrial uses, principally steam making. If we eliminate households we may assume that 25,000,000 tons of the 50,000,000 tons are used for making steam, so that of the total 77,000,000 tons of anthracite, we may say that 52,000,000 tons, or 67.5 per cent., are used for steam production.

*"Coal in 1915," by C. E. Sesher, published by the U. S. Geological Survey; Part A on production.

Table IV shows to what point the [illegible] must be raised to obtain the saving of 10.65 per cent. upon which [illegible] are based. The poorly run boilers would of course be most receptible to the greatest improvements. Hundreds of boiler plants operate at no greater than 58.07 per cent efficiency, and it is a comparatively simple matter to bring them up to an efficiency of 70 per cent or higher. The latter would result in a saving of over 17 per cent of the coal.

If we do not limit our action to coal used for steam generation, but extend it to include economy with which the steam itself is utilized and applied, the predicted saving could be doubled, so that we might save 2,000,0000 fifty-ton carloads of coal per year. There is, for instance, widespread ignorance to a surprising degree in regard to the value of exhaust steam in heating and process work. The coal-consuming public should be taught that a heating system which requires 100 boiler horsepower may insert a steam engine between boiler and heating main and obtain nearly 100 mechanical or electrical horsepower in addition to the required heating for about the same consumption of fuel.

Steam plants are under the immediate management of chief operating engineers. The examination requirements for licenses in this profession call for practically no knowledge of steam and fuel economics. These examinations deal chiefly with matters of safety, repair and maintenance of equipment and neglect almost entirely the subject of coal economy. This is a very serious defect in our present system and is directly responsible for a large preventable waste of fuel.

The mining and distribution of our coal supply, the regulation of prices and the adjustment of financial and labor problems have already been placed under official administrative attention. But no parallel measures have been adopted looking toward reduction of waste in connection with the utilization of this coal.

### Discussion of the Paper

Walter N. Polakov: The invitation to discuss the means and methods for reducing waste of coal is very welcome since all that has been said and done so far has failed to produce tangible results.

Last April I brought out the impending danger of a fuel famine and soon afterward the movement was on the way affecting at that stage only coal production, transportation and prices.

Being limited in its scope and nature, it did not embrace at that time the third group of my original recommendations concerning the use of fuel. My editorial in "Coal Age" of July 14 and articles in other magazines emphasized this paramount task "to start at once the movement for the efficient utilization of every available supply of fuel."

A couple of months later Mr. Garfield publicly admitted that the principal hope for a solution of the coal problem lies with the people themselves: "They must save every possible bit of fuel."

Saving may be carried out along two lines—either on the principle of German "Spar Kasse," inevitably limiting the industrial productivity and impairing the health of the people, or on the principle of more efficient utilization of fuel, producing more power and heat with less coal. Only this latter means of saving is to be considered.

The inauguration of efficient management of power plants cannot be accomplished overnight. It requires study in each plant of its peculiar conditions. It requires careful training of firemen and other employees. It necessitates an adequate stimulation of employees to continually maintain the highest degree of efficiency. To do it no capital investment is needed. It is not a matter of better furnaces, of mechanical stokers, or other cures preached by salesmen. It is a matter of knowledge and method.

There are already many plants that have reduced their coal consumption from 20 to 40 per cent for the same output by better organization of power-plant work. There is no need to here describe these principles and their results. "Task Setting for Firemen," a paper presented before this society in 1913, "Planning the Power Plant Work," a paper delivered before the Taylor Society, and numerous other contributions describe the nature of my work and fundamental principles more or less at length. Van H. Manning, Director of the Bureau of Mines, recently took the view advocated by me for years. Said he: "The immediate problem is a difficult one. We cannot scrap all out-of-date power plants. We must start by doing the best with what we have. We must begin saving coal at once. The problem is a peronal one. It deals with the human elements. We must reach the man with the shovel."

Mr. Myers presents for discussion two plans. The first one is unfortunately worded so as to create prejudice against it. It reads " . . . . the use of authority to compel coal consumers to execute such measures of economy as the proper authority might prescribe in any given case." It sounds Prussian. But is it? Does it mean imperialistic, arbitrary authority or an authority of an expert based on scientific knowledge of facts, similar to the authority of a doctor prescribing treatment?

TABLE III.—COAL USED ON LAND FOR STEAM PRODUCTION IN PERCENTAGE OF TOTAL PRODUCTION

| Bituminous | % |
|---|---|
| 1. Railroads, item 1, Table II | 28.0 |
| 2. Domestic and steam trade, assume only one quarter of item 7, Table II. | 4.0 |
| 3. Industrial steam trade, item 8, Table II. | 33.0 |
| 4. Steam and heat at mines, item 10, Table II. | 2.0 |
| 5. Total bituminous | 67.0 |
| Anthracite | |
| 6. To steam making | 67.5 |

Hence it may be assumed that 67 per cent. of all the coal produced is used for making steam on land.

To save 10.7 per cent. of the coal consumption necessitates the raising of any combined efficiency of boiler and furnace from that shown under Old Efficiency in Table IV. to the corresponding value under New Efficiency in the same table.

The strength of England, France and even the Central Powers is due to the co-operation in industries. Those who fail to render the service to the common cause are denied the privilege to mismanage their plants. True enough, this co-operation is regulated by the state

and at times compulsory as is conscription or commandeering of productive facilities or commodities. The voluntary co-operation for which we long will come only after the war as a result of new social readjustments. But we cannot wait. The problem is of to-day. To-morrow may be too late.

In other words we must create conditions stimulating voluntary co-operation even under individualistic regime.

The plan therefore means the abolition of privilege to waste fuel in inefficiently conducted plants, by giving priority in coal deliveries to those who prove that they use it efficiently.

At present a wasteful plant gets an excessive amount of coal, while the highly economical one stands an equal risk of being shut down for the lack of coal. If the efficiency is protected by priority, it will work also as a stimulus for the wasteful ones to find means to improve their methods and then ask for a new rating.

Such encouragement of efficient plants, rendering good service to the country and stimulating the inefficient to seek their salvation through the means beneficial to the country can be accomplished along the following lines:

Rating by experts (nominated by the national engineering societies and supported by public opinion and Government) of plants in the indispensable industries who are entitled, because of coal-saving methods in use, to the priority in coal supply.

Receiving of applications by the special service bureau of American Society of Mechanical Engineers, from the low-rated plants for assigning the expert help.

Serving the needs of such inefficient plants by offering services of recognized experts in power-plant management for direction of the work.

Organizing a staff of steam, electrical and combustion engineers, whose members will be assigned to carry out the work in the plants of the applicants under the direction and supervision of experts.

Charging for such services an adequate compensation to cover the expenses involved (salaries, traveling and office) but no profit.

Mr. Myers' second plan, "an educational one, in which patriotism and efficiency would furnish the motive forces required," is in my opinion doomed to failure for the following reasons:

Teaching efficiency by a correspondence-school method will accomplish little good, is incompatible with the professional dignity of this society and lacks the personal touch.

Endless variety of equipment, grades of fuel available, personality of men, nature of load, climatic conditions, etc., make the preparation of "simple instruction sheets for engineers and firemen" impossible and if made they are so general as to be useless. Failure of the Massachusetts fuel board in such an attempt is a joke among power-plant men in this section.

No instructions of real value could be given unless examination of the plant was made. Selling patent medicines curing all diseases ranks with fake only too often not to make one careful.

Keeping records, logs, etc., necessitates instrument equipment and measuring devices; all of this is good only when the data are used and interpreted by a trained man and this is done continually. Too many plants have no instruments at all; most of those that have keep them as ornaments owing to the lack of proper organization.

If the regular employees failed to secure high efficiency it is not because of the lack of "circularized education," but chiefly on account of lack of time to carry on investigations and tests, all the time being absorbed by routine duties; absence of instruments, facilities or encouragement; lack of experience in this highly specialized line of research work.

The education must begin with owners and managers, not with the firemen.

The very principle of "teaching" and "instructions" given to manufacturers and plant owners by the society is undemocratic and un-American. They do not want or need "to get something for nothing." Producing for the country but not without profit they can prefer to pay for what they get if the benefit is commensurate with the expenses.

"Educational" talks and circulars usually degenerate rapidly into debating societies, wasting time needed for deeds.

Any half-measures with good intentions falling short of accomplishing valuable results are dangerous as they chloroform the public conscience, creating a belief that something real is being done while there is little behind the words that make all content.

To sum up, the problem is to be solved by groups and individuals availing themselves through this society of services of those who know how more power can be gotten out of a pound of coal. There is no necessity to compel plant owners to improve their methods since in such a step lies their self-preservation. But there is an urgent necessity from the national viewpoint to conserve the fuel by preventing its waste by ignorance or indifference. The valuation of plant methods to establish ratings for priority in coal deliveries is therefore recommended.

Albert A. Cary: Mr. Myers endeavors to focus our minds upon this panacea in the statement that "the saving or wasting of one-fourth of the coal consumption of our industries depends entirely upon the efficiency of its operating management," and this seems to be the text upon which the balance of his paper is founded.

To secure the desired conservation of fuels in such plants, Mr. Myers advises the services of the expert in operating management. Provided he understands his business, such an expert can undoubtedly secure desirable fuel savings; but results depend largely upon the co-operation he receives from the plant owners and their employees, as well as their willingness to equip plants with the needed apparatus and to use them continuously after the expert concludes his work.

[illegible] PER CENT. SAVING IN COAL

| Old Efficiency Per Cent. | New Efficiency Per Cent. | Old Efficiency Per Cent. | New Efficiency Per Cent. |
|---|---|---|---|
| 44.67 | [illegible] | 62.54 | 70 |
| [illegible] | [illegible] | 67. | 75 |
| [illegible] | 60 | 71.47 | 80 |
| [illegible] | 65 | | |

Saving of [illegible] same output of [illegible] New Efficiency [illegible] Old Efficiency

New Efficiency
and increase of steam production for same coal
New Efficiency — Old Efficiency

| Old Efficiency | | | |
|---|---|---|---|
| 44.67 | 50 | 62.54 | 70 |

To illustrate, I will refer to the plant of one of my clients, the Tennessee Copper Co. By redesigning the furnaces in this plant and adapting them to the fuel used and by substituting machine-fired grates, they have since succeeded in obtaining the same amount of steam with but 64 per cent of the Jellico coal formerly used. This plant, when completed, was turned back to same management that it had before with no further instructions. There were installed facilities for continuously determining the weight of the coal, ash and water used as well as the analysis of the furnace gases.

In another large industrial plant a similar saving in coal was effected. This plant has an aggregate capacity of over 7,000 nominal boiler horsepower, divided into 22 units. It was formerly operated with hand-fired shaking grates for which machine-fired grates were substituted with properly designed furnaces. The plant is now being operated continuously at 150 per cent. rating and is using no more fuel than it formerly did when being operated at two-thirds of its present output. The boiler-room force required to operate this altered plant is less than half of the number of men formerly required. No change has been made in the management of this plant.

Proper furnace design and construction, flue and draft-producing equipment adapted to the use of the particular kind or quality of fuel used is the keynote of the question of fuel conservation.

Furnish the mason with complete instructions for "laying up" the brickwork and properly bonding the interior and exterior walls of the furnace so that the large difference in temperature between the two sides will not, by unequal expansion and contraction, rapidly destroy these furnace inclosures and so waste fuel by infiltration of air.

The selection of material used and its method of erection should never be left to the mason, as it is safe to say that fully 90 per cent of the masons erecting furnace settings are hopelessly un-

coal fed to produce a proper setting. After equipping the plant with proper furnace settings which are adapted to produce the highest possible efficiency with the particular fuel available, the expert in operating management can come into the plant to instruct the men.

To meet the present emergency, I propose that the War Coal Board bring all the firemen in this country under its control by requiring them to take out United States licenses. The various state, county or municipal governments can assist them in this work. The applicants for these licenses must show some qualifications that would entitle them to hold such privileges, but it is doubtful whether it would be possible, at the beginning, to have all these applicants examined before qualified examination boards.

Future applicants should be required to pass an examination before such boards and qualify in a satisfactory manner before receiving their licenses. Any operator of a coal-burning plant (domestic plants, of course, excepted) who operates his equipment without a licensed fireman should be liable first to fines and finally to more severe penalties.

Each license should be issued for the applicant to operate in a definite, described plant and nowhere else. Should the fireman leave this plant for any good reason, rather than for incompetence, he can take his license to the proper authorities and have it transferred to another plant where he has found re-employment.

Should the fireman be found to be incompetent, his license should be revoked and future applications be denied.

Inspectors appointed by the War Coal Board might visit from time to time the various coal-burning plants, and should they find any of them using fuel wastefully, a notice should be served upon the owner. If this is not followed by prompt action to reduce or stop the waste, the fireman's license should be revoked.

The foregoing is proposed as a war measure.

Professor L. P. Breckinridge told of the methods used in Connecticut to conserve coal, stating that meetings were held to which the public was invited, to be told how to burn coal economically in house and power-plant boilers. Norman Reinicker believed that fuel economy was much more a matter of design than education of firemen. E. N. Trump emphasized the value of bonuses to firemen to give incentive for economical use of coal.

## PERMISSIBLE TEMPERATURE OF COAL PILES

THE permissible temperature which a coal pile can be allowed to attain, according to the "Travelers Standard," is 150 degs. F., this having been adopted in a number of cases as a standard and no serious trouble experienced so far as is known.

It is conceivable, however, that there might be an appreciable diminution in the calorific value of the coal if it were subjected to prolonged heating at a temperature approaching 150°, even though actual ignition did not take place. It is therefore recommended that a maximum temperature of 130 degs. F. be allowed, which will probably be safe under almost all conditions.

Under certain conditions a considerable rise in temperature may take place within a short time. A rise of this kind may stop before it reaches the danger point, but, on the other hand, it may continue and result in spontaneous ignition; therefore, if such a rise is observed, steps should be taken immediately to check it. A recent case is illustrative of the conditions that may cause such a sudden rise in temperature. At a certain plant a steam pipe passed through a coal pile, but it was not expected that this pipe would cause any trouble because it was heavily insulated with a covering of 85 per cent. magnesia. Nevertheless, a rapid rise in the temperature of the coal pile was noted (the coal at this particular plant being under close observation for the purpose of detecting possible heating), and thereupon the steam was shut off before the danger point was reached.

## STEAM TURBINES v. DIESEL ENGINES

IT is sometimes remarked as a curious fact that the Diesel engine, whose fuel is oil, finds little favor in the oil regions of the United States. The explanation is, of course, that where fuel is cheap, the most economical type of power plant is one which entails the lowest first cost and the lowest maintenance charges rather than one which can show the highest thermal efficiency. This is one particular instance of the way in which the various factors which determine the choice of a prime mover vary according to the locality and to the conditions of each separate case. Another consideration, which may in extreme cases become decisive, is the load factor of the plant. Obviously, if a power plant is to work only intermittently, the extra capital charges on a highly efficient plant may easily outweigh the saving on the fuel due to the greater efficiency.

The cost of water is another factor in the equation. As between the Diesel engine and the steam turbine scarcity of water will sometimes turn the scale in favor of the Diesel, even when other weighty factors are against it, since about twelve times as much water is required for condensing purposes with steel turbines under general conditions as is needed for jacket cooling with a two-stroke Diesel engine, while four-stroke engines need only one-twentieth the water. In a paper read before the American Institute of Mining Engineers, Herbert Haas sums up concisely the economic considerations governing the choice between steam turbines and the Diesel engine in Western America. Where fuel is dear and the load factor is high, the Diesel engine has the pull; where contrary conditions exist the steam turbines come out the best except where the instant readiness of the Diesel engine gives it preference, and installation cost is of secondary importance. Here it is necessary to balance the cost of keeping boilers under steam continuously against the difference of interest charges of steam turbine and Diesel engine plants. For power plants erected at the source of the fuel either on the oilfields or at the coal mines prime movers will be selected costing least to instal, i.e., steam turbines, since fuel expenditure will weigh less than interest and redemption charges.

In many cases combination plants using Diesel engines for supplying power continuously against the constant main load, and steam turbines for furnishing periodically occurring peaks by the same use of high duty boilers with large water and steam spaces, capable of being forced when necessary, will prove most profitable. Up to capacities of 1,000 horse-power steam turbines can compete with Diesel engines only in special cases, such as supplying exhaust steam for heating purposes. For such small units, particularly for greatly varying loads, reciprocating steam engines are preferable. For larger plants than from 1,000 to 10,000 kw. capacity careful analysis must be made of the relative advantages of Diesel engines and turbines, a knowledge of the load factor, fuel prices, and water conditions being necessary. For power plants larger than 10,000 kw. using units from 6,000 kw. upward steam turbines have the preference, unless a combination of high load factor, high fuel cost and poor water conditions favor a Diesel plant.

## OILING MACHINERY

INSTEAD of going over machinery with an oil can in hand it is now possible to oil it automatically. Geo M. Rogers, of Chicago, has invented an oiling apparatus which is operated by electricity and which can be put to work at any time by setting the mechanism just as one would set an alarm clock.

The oiler has a cup with an oil-feed opening in the bottom. An oilfeed pipe is connected with the cup and a plunger rod is so arranged that it gives vertical movement in the cup. A valve fitted at the lower end of the plunger fits the opening when the plunger rod is lowered. A guide pin extends downward from the valve and a gasket adapted to bear on the bottom of the cup when the plunger is lowered is arranged under the valve. The valve and plunger are operated by electricity.

If it is desired, an electric light may be included in the circuit which operates the oiler so the attendant may be able to watch the operation.

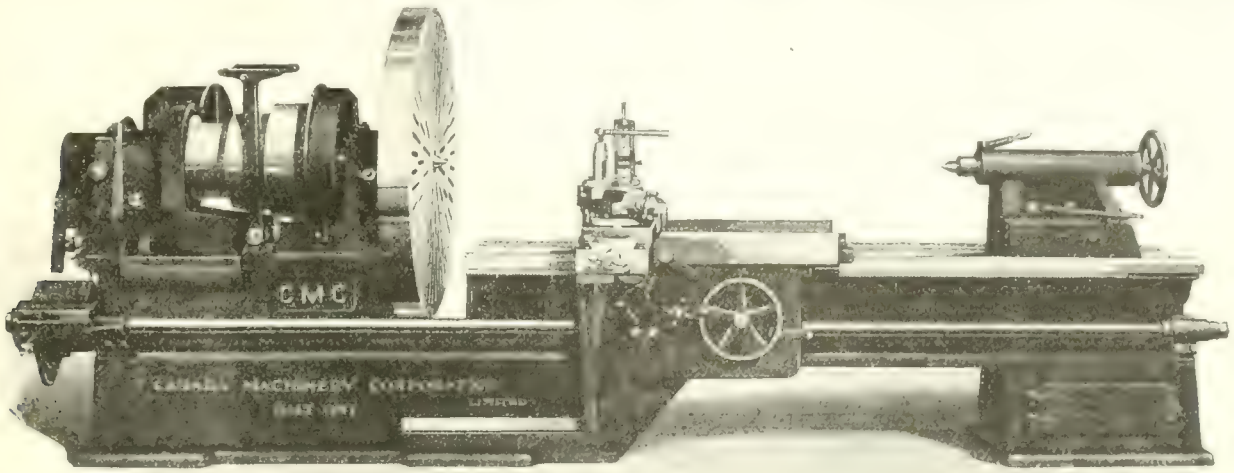
WITH universal grinding machines, which are relatively light and frail in construction, a wheel of narrow face is always used and is most satisfactory. On modern machines, of more massive construction, wheels of wider face may be used, and a greatly increased production thereby secured.

# PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

## 26 in. QUICK CHANGE GAP LATHE

AN improved gap and gap plate permitting the large face plate and thin work to swing without removal of the plate, a bed of unusual weight and strength, and a saddle having a bearing on the flat surface inside the front vee in addition to the two vee bearings are outstanding features of the gap lathe illustrated in the accompanying engraving and built by the Canada Machinery Corporation, Galt, Ont.



26 IN. QUICK CHANGE GAP LATHE WITH DOUBLE BACK-GEARED HEADSTOCK AND CONE BELT SHIFTER

The three-step-cone double-back-geared headstock is fitted with a large diameter spindle (front bearing 4⅜ in. by 8¾ in.) equipped with split phosphor bronze bearings having large oil wells. Special high carbon spindle steel is employed, and a 2⅛ in. hole is drilled throughout its length from the solid, while the bearings are ground to size. The extra wide steps on the cone enable large belts to be used, insuring ample power for the size of lathe.

Box section cross ribs brace the bed, which is provided with three vees of liberal proportions. The headstock and the tailstock each rest on one vee and one flat urface, while the saddle bears on two vees and also on the flat surface. The brackets attached to the bed are tongued and grooved in position.

The feed (5 to 160) and screw cutting changes (2 to 64) are obtained through quick change gear, the required positions of the lever being shown on an index plate. The thread on the lead screw is intended for screw cutting only and provision is made to prevent the engaging of either the automatic cross feed or longitudinal feed when the machine is set for screw cutting, or vice versa. The feed reverse lever is located on the apron, and the lead screw is reversed for right or left hand threads by reverse plate on the head.

The saddle is particularly substantial, has great strength in the bridge and has supporting strut resting on machined slide on bed for use when facing large diameter. A thread chasing dial for indicating thread engagement points avoids stopping the lathe when screw cutting, while the handles of the cross feed and compound rest screws are graduated in 5/1000's and 1/16's of an inch. The base of the compound tool rest is graduated in degrees.

The tailstock, of heavy design, is shaped so as to afford ample clearance for the compound rest when set at right angles. The spindle (3⅛ in. dia.) is graduated in fractions of an inch for boring, and set over adjustment is provided for taper turning.

Standard equipment includes countershaft with two friction pulleys and shifters, special cone belt shifter, follow rest, steady rest, one large and two small face plates and necessary wrenches. Special attachments such as taper attachment, turret on the bed or saddle, turret tool post, etc., can be supplied.

Motor drive is also provided for, either direct by variable speed motor or through an all geared head by constant speed motor on single pulley.

This lathe is furnished in both 26 in. and 32 in. sizes, having principal dimensions respectively as follow: swing over gap 46 in. and 52 in.; width of gap clear of face plate, 18 in.; swing over saddle 17½ in. and 21 in.; distance between centres, 10 ft. bed, 4 ft. 6 in. and 3 ft. 4 in.; width of belt, 5½ in. and 6 in.; weight of machine 10 ft. bed, 7,030 lbs. and 9,400 lbs.

## MULTIPLE SPINDLE CHUCKING MACHINE

THE machine shown in the accompanying engraving is a recent product of the New Britain Machine Co., New Britain, Conn., and although designed to handle much of the same variety of work as the regular single head automatic machine, exhibits two main points of difference, viz.: (a) The work is held and revolved by the spindles, the tools being fixed in the tool slide; (b) The use of cross slide tools is thus rendered possible, a feature lacking in the regular type in which the work is held stationary.

The spindles (six in number) are of liberal diameter, hammer-forged from chrome nickel steel, heat treated, hardened and ground, and run in bronze bearings of ample proportions, ground straight inside and taper outside, thus providing means for taking up wear without disturbing the alignment or original accuracy of the machine. Ball thrust collars are provided on all six spindles for taking care of the end thrust due to tool pressure, this arrangement resulting in a thirty per cent reduction in the power required to drive the spindles.

Five rates of spindle speed and twelve variations of feed are provided by means of change gears.

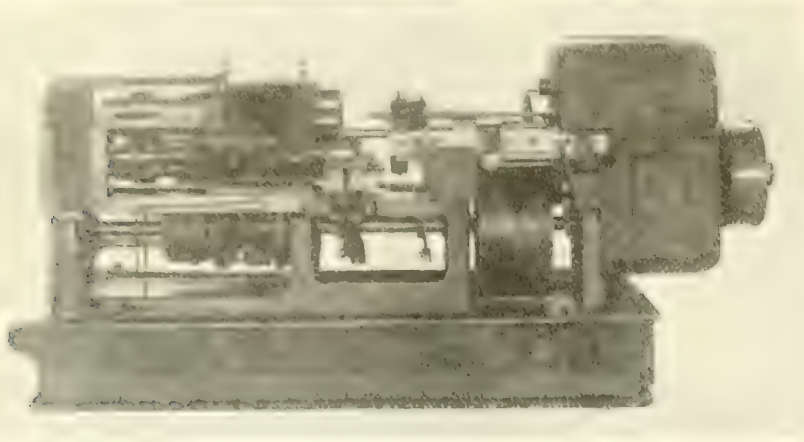
The spindle cylinder is heavy in design and is housed in a split housing with a loose cover permitting easy access to spindle-hearing adjusting nuts. The indexing mechanism, patterned after the Geneva motion, gradually accelerates the heavy spindle cylinder at the time of indexing, and as gradually checks its motion without shock, final accuracy in indexing being insured by means of an extra wide rectangular

ential (hurry-up motion) which indexes the spindle cylinder and operates the finished cutting, is regularly fitted to this machine. The spindle cylinder is always indexed at constant speed irrespective of production and spindle speed.

and at the feed cam is taken by a hardened steel roll fixed to the frame and bearing against the edge of the drum.

Standard tools, drills, reamers, etc., are used the direction of spindle, rotation being right handed.

A quiet, smooth-running machine results from the cutting of most of the gears by the generating process and



MULTIPLE SPINDLE CHUCKING MACHINE

Draw-in spring collars of special design are employed, operating satisfactorily where pieces do not show a variation exceeding 1-32 in. in diameter. If there should be a greater variation than this, parts should be sorted into lots and the spring chucks adjusted to each lot. The machine is regularly equipped with a hand wheel for operating the spring chucks for holding work, but when desired the machine may be equipped, special, with an air-chucking attachment provided with a cylinder of large size insuring successful operation on low air pressure. This device makes chucking a simpler, easier, and quicker operation, resulting in the acceleration of production where the operations are short.

For the better protection of the operator, the spindle is automatically disconnected from the drive during loading and unloading. A threading attachment may be installed in the fourth tool slide position and for work which is to be handled by means of a chucking lug and which requires no threading, the machine may be arranged to index in the opposite direction (clockwise), thus bringing the finished article to its final position opposite a cross slide which may be fitted with a cutting-off blade.

The tool slide is of extremely rigid construction and is so designed that the thrust of the work above and below the center line is evenly balanced, thus eliminating any cramping strain upon the tools. The tool slide cam, being laminated in a similar manner to a leaf spring, one cam, through its adjustment, is sufficient for all lengths of work within the capacity of the machine. The cam shaft is driven through a large internal gear on the inner circumference of the feed cam drum. The thrust of the tool slide from the absence of all chains and bevel gears.

Hand control levers on each side within easy reach of the operator enable the power feed to be instantly stopped or started. These, in connection with a hand feed crank for testing all feed movements and tool positions, are valuable features avoiding breakage in setting up, testing and adjusting tools.

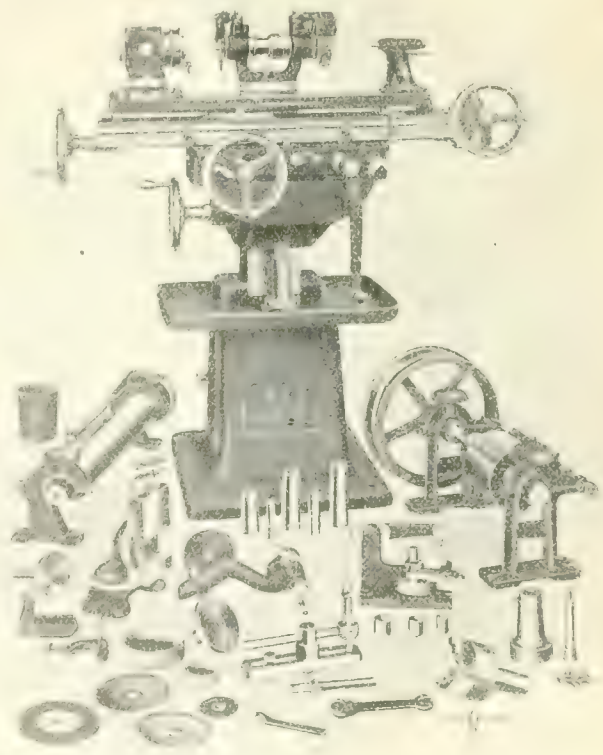
The elimination of much of the exterior piping for the oil distributing system is accomplished by conveying the oil through the underside of the toolslide into a chamber at the centre surrounding the driving shaft bushing, from which it is tapped off at intervals through short tubes to the individual tools. The oil pumps runs at constant speed.

The base, forming the chip pan, extends to the floor, thus dispensing with legs, and the broad foundation thus obtained, together with the stiff construction and ample weight of the machine, tends to prevent vibration, and insure smooth, accurate work. That portion of the bed directly beneath the work has a 45 degree slant toward the rear of the machine so that the chips are carried to the side as they are cut off. The chip pan is widest on the rear side, and slopes toward the rear end where there is an oil well and strainer, from which the oil is pumped and distributed to the work. This construction permits the draining off of the oil before the chips are removed and makes it possible to rake out the chip pan without stopping the machine or removing the splash apron.

Machines may be equipped with either belt or motor drive.

## CUTTER AND TOOL GRINDER

THE cutter and tool grinder, shown in the accompanying engraving, when furnished as a universal machine and equipped with attachments for gear cutter, cylindrical, internal and surface grinding, will grind all work that comes to the toolroom such as jig bushes, straight edges, snap gauges, slitting knives, reamers, rose bits, formed tools, etc. The design of the machine is such that unusual rigidity is obtained, while convenience of handling and accuracy of operation have been studied in the arranging of handwheels and levers. The machine is constructed with a heavy pyramidal base having large floor bear-



UNIVERSAL CUTTER AND TOOL GRINDER WITH COMPLETE OUTFIT OF ATTACHMENTS, ETC.

ing, to which the column is bolted. The column is of substantial box section and its front face is provided with dovetail slide to which the knee is gibbed, thus overcoming inaccuracy such as may arise where operating parts are swivelled around a column of small diameter.

The box form knee is closed in on top and bottom, affording maximum resistance to all torsional and bending strains, while a solid and accurate bearing during the life of the machine is assured by an adjustable tapered gib. The saddle slide on the top of knee has broad vees 16 inches apart giving unusual support against rocking of the saddle, while extensions of the saddle bearings protect the vees from dust in all positions.

One long straight bearing aligns the slide to the saddle, with full length dovetail taper gib. Both "degree" and "taper" per foot" graduations are provided, the taper adjustmemnt being operated by a fine thumbscrew in front of table.

Ample bearings support the table in the middle and both ends. When grinding at right angles to wheel it is unnecessary to swing table beyond end supports, as the wheel head swivels on column 180 degrees on either side. The spindle is hardened and ground and runs in dust-proof taper bronze bearings with adjustment for wear carried in a heavy head.

Fast and slow longitudinal feeds are obtained instantly by lever in front of saddle, the fast feed operates by long lever either from front or rear of machine through rack and pinion, and slow feed operates by large diameter hand wheels on both ends of table through screw and half nut. Ball bearings on the slow feed mechanism insure smoothness of operation and avoidance of chatter on work.

Cross feed is operated by large diameter hand wheels either front or rear of machine, and vertical feed by handwheel on side of knee. All [illegible] bearings and all feeds have micrometer dials.

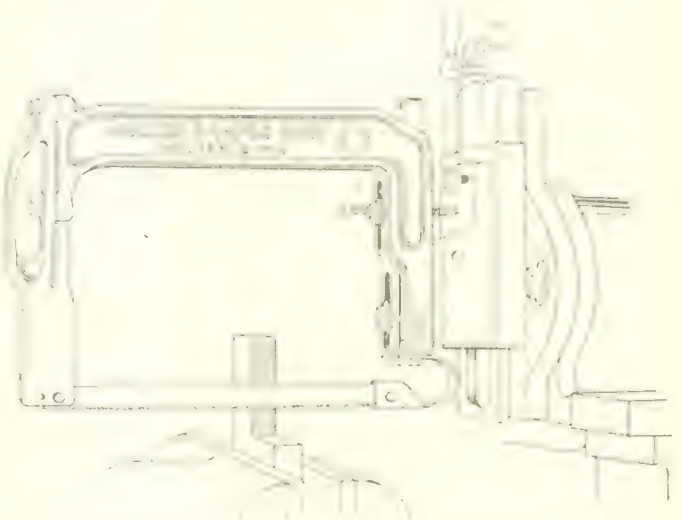
A special type of universal tooth rest is furnished having two blade suports, one flexible for use with straight fluted reamers and cutters, and one rigid for spiral fluted mills, hobs and similar work. Provision is made on the wheel head as well as on the work head for fastening the tooth rest either above or below the work to be ground, thereby giving the operator the option of grinding the tool with the grinding wheel revolving either against the cutting edge or away from it.

The illustration shows the drum countershaft for cylindrical grinding attachment, internal grinding attachment, and attachments for surface grinding and gear cutter grinding, also regular type of countershaft supplied.

This machine is the product of the Oakley Machine Tool Co., Cincinnati, O., and its range covers 17 in. longitudinal movement, 10½ in. vertical movement, 9 in. cross movement. Net weight of plain machine is 1,175 lbs. and of universal, 1,290 lbs.

## SHAPER SAW

THE accompanying illustration shows an attachment whereby the ordinary shaper may be converted into a power hack-saw, thus making it into a general utility tool of considerable adaptibility and usefulness. The combination of hacksaw and shaper possesses the advantages of: (a) powerful variable stroke; (b) variable speed range for different qualities of stock; (c) positive feed without dropping in changing wall thickness or at the end of the cut; and (d) the universal grip on articles afforded by the shaper vise and table.



SAW FRAME ATTACHMENT FOR USE ON SHAPING MACHINES.

The use of the entire blade and the securing of uniform wear throughout its length is ensured by the easy adjustment of the shaper ram as regard length of stroke and position in relation to the work on the shaper table or in the vise. This attachment may also be used where work of a large or bulky nature, which could not go in a milling machine, is to be sawn.

The saw frame is made in two parts, an adjustment shoe being provided for the purpose of tightening and aligning the saw blade. The frame is held in position by a screw entering a nut block inserted in the tool post block, or clapper of the shaper. The saw is held in position at the shaper end of the frame by a guide spring which by allowing a certain amount of oscillating movement prevents the blade from breaking.

A set screw with a five inch limit provides for the adjustment of the tripping motion of the saw and also provides a means of making the frame rigid with the shaper ram if desired. The frame has a 9 in. clearance to the cutting edge and can be fitted to shapers with a 16 in. to 24 in. stroke. The device is the product of J. A. Moller, New Rochelle, N.Y., who makes it in two sizes, No. 14 measuring 12 in. x 17 in. overall which takes 14 in. by 1 in. by 1/16 in. blades, and No. 18 measuring 12 in. x 21 in. overall which takes 18 in. by 1 in. by 1/16 in. blades.

## SCIENCE AND WAR HORRORS

THE necessity for arousing mankind, and especially that portion of it concerned with engineering progress and applications of science, to the danger attending the conscienceless development and utilization of the powers placed at our disposal by science was emphasized in the address of Dr. Ira N. Hollis on the occasion of his retirement from the presidentship of the American Society of Mechanical Engineers.

"Unless some conscience is aroused that science is not to be used against man, but for him, then it will never be safe for this world," said Dr. Hollis. "It is our task to assist in making the world safe against the forces that we have unloosened, so that the century may not close with a total failure of the civilization of Christian races. It is we who have developed the application of science, and it is we who are using it to destroy one another, forced into the struggle by the rulers of a nation that knows no right except might, and no mercy except that which is taught them by the sword.

"The twentieth century is still young, and we do not yet know what it will represent to the future historian. Will it be the debauch of science or will it mean a new birth to Christianity? It is the engineers' task to decide this. There are two tendencies; one towards greater comfort and luxury, and one towards greater service. The first can plunge us only deeper and deeper into war for the control of a commercial output. It can only bring us more firmly under a governing class devised either by birth or by commercial success. The second means the complete emancipation of the individual trained to think of service as the chief source of good government and happiness in life. The only theory that will hold men together is that of service."

IN grinding gas engine cylinders on the cylinder grinding machine, it is customary to run water through the jacket, or over the outside of the cylinder to maintain an even temperature. The purpose of this is to keep the cylinder from changing shape on account of heating up and to make it possible for inspectors to properly guage the cylinder an hour or a day after it has left the machine. Water is not used in the hole where grinding is being done as the machine works more satisfactorily grinding dry than wet.

## FUTURE INTERNATIONAL TRADE

THE British Government is considering legislation designed to frustrate future German attempts to control the metals of the world; members of the Chamber of Commerce in Paris have banded themselves together to secure due recognition and utilization in France of French manufactured goods through the medium of a national trade-mark; the United States will soon be in possession of a mercantile marine which in post-war days will be a splendid counterfoil to German overseas trade activity, and Canada is following the lead of her big neighbor in a manner which not even Germany will be able to ignore.

The ultimate effect of all these developments on the international trade of the world can and must be anticipated as far as it lies in our power to do so. Germany realizes that, whatever governments may or may not do, the commercial powers of the various countries will not, during the life of the present populations, consider, let alone accept, overtures from Hun merchants. Her resentment at this certainty is evidenced by the commercial organ, Berlin Tageblatt, which says: "As far as Germany and her allies are concerned, we shall have to insist at the peace negotiations that discriminatory laws like these, which can only lead to endless reprisal legislation and must result in poisoning the whole economic atmosphere, are abolished by the treaty of peace."

The peace negotiations, however, are not yet, and when they do arrive the chances are that Germany will crave instead of insisting. If one cares to examine the list of peace conditions which Germany was prepared to offer France in the early months of the war, it will be found that complete control over France's fiscal policy for a term of twenty-five years was one of the long cards in the game. Why, therefore, should Germany object to the Allies controlling only their own policies—they will not need to care about Germany's?

Self-protection is the first law of nature; it was also Germany's national motto, plus subjugation or destruction of competitors.

Self-protection, minus the diabolical appendix, has been forced on the nations of the world, and that which has been learned in the heat of battle and ground into our flesh and blood will not only be remembered, but must be amplified, developed, yea worshipped, as the chief end of each nation, firstly to itself, that it may care for its defenders and recover from the struggle, and secondly to its companions in arms that their brotherhood in the struggle may be cemented in the days of peace to come, beyond all hope of future severance.

The attitudes of the various countries are peculiarly typical of their national temperament. Britain prepares a bill, not to create a monopoly, but to prevent future attempts in this direction by our present enemy. France, more virile and intensive, proposes the adoption of a national trade-mark, the use of which will be necessary by every French manufacturer, so that all products not bearing it will be recognized as either imported or manufactured by other than French makers in France. The exclusion, in addition to applying to goods not entirely made in France, is seemingly also directed against those made in France by other than French capital and labor.

The rapid development of this national sentiment is shown by the decision of L'Exportateur Francais, a leading trade paper which will not accept any advertisement nor open its columns in any form to any manufacturer who does not belong to the trade-mark society.

Former abuses of commercial hospitality by German interests are now exerting the inevitable recoil effect and in trying to dodge the eternal law of action and reaction they are already planning subterfuge and misrepresentation, through the conveniently neutral Sweden, but their evil genius has followed them there and the adoption of a national trade-mark similar to that of France is actively urged in that country.

In the address which R. J. Younge delivered recently before the Manufacturers' Association, the problems awaiting our industrial leaders are effectively enunciated. "How," he asks, "are we as a nation going to meet our national obligations after the war, unless we build up a balance of trade by greater production and wider markets? ....All this progress will be in vain unless we can gather it up and nationalize it."

## CANADA'S FUEL CONTROL ORDER

THE recent order of the Dominion Government suspending the operation of manufacturing plants for three days and the further restrictions placed upon theatres, clubs and other places of amusement brings home to the people of this province our dependency upon the United States for our fuel and also calls attention to the urgent need of conserving what fuel we have. It is needless to add that every manufacturer or other user of power, large or small, has a very clearly defined duty to perform in this regard.

Proper firing, clean boilers, well lagged steam lines and all other improvements effecting economies in various ways, not only are directly to the manufacturers' advantage but are of direct intrinsic value to the country at the present time.

According to first reports the Canadian order goes considerably farther than the American in some respects in that all munition plants must close for the three days.

# INDUSTRIAL NOTABILITIES

EDWARD GIBSON MACK, managing director, Crouse-Hinds Co., of Canada, Ltd., electrical manufacturer, Toronto, was born in Auburn, N.Y., March 19, 1887, son of Edward G. and Martha Reed (Coe) Mack, and attended high school at Syracuse, N.Y.

In 1900 he entered the employment of the Crouse-Hinds Co., Syracuse, as office boy, and worked through the various departments of the business until

EDWARD GIBSON MACK

1904, when he became traveling representative for the company for the eastern part of the United States and Canada; this he continued until 1910, and in 1911 came to Canada and organized the Crouse-Hinds Co., of Canada, Ltd., of which he was appointed managing director.

Mr. Mack was elected member of executive council (electrical section), Toronto Board of Trade, 1918, and is also member of Canadian Manufacturers' Association.

He married Marian Ward, daughter of John F. Ward, St. Paul, Minn., August 20, 1913, and has one son.

His clubs are National; Lakeview Golf; Parkdale; Canoe (Toronto); Citizens'; Amherst Athletic; Anglers' Fishing (Syracuse, N.Y.). His societies are: Electric Jovian Order and Electric Club (Toronto); A.F. & A.M. (Central City Lodge); Elks (Syracuse).

Fishing, hunting and motoring are his principal recreations. He is Presbyterian in religion.

Mr. Mack's residence address is 265 Glenlake Avenue, West Toronto, Ont.

# Three Day Close-Down Order for Ontario and Quebec

*Fuel Controller Issues Order After Consultation at Washington—Further Orders Expected if Necessary—Munition Plants Included—Iron and Steel Trade Still Affected by Weather—Spelter Prices Fixed in United States.*

The fuel regulations, while being in a measure drastic, will help considerably to relieve the fuel situation which has become acute. Only Central Canada is affected by the order as this is the section of the country which obtains practically all its fuel from the United States. The saving in coal during the three days February 9, 10 and 11 will be considerable and the railways will be able to concentrate on the movement of fuel. The continued severe weather is making railway operating extremely difficult and the movement of freight is slow. Deliveries of materials of all kinds are hindered by the congestion of freight in the yards and at the border, with the result that many industries are handicapped by the delay in receiving raw materials and in shipping the finished products. The coal situation as a result of these conditions continues acute while coke also continues in short supply. Foundries and furnaces are in need of coke and capacity operation is impossible under prevailing conditions. The steel plants likewise are suffering by reason of the coke shortage and the cold continues to curtail production. Conditions prevailing in the United States in this respect are much the same as in Canada. Production of iron and steel has fallen off while the demand is as insistent as ever. As a result of these conditions the available supply of steel and iron has diminished, leaving a comparatively small tonnage for consumers not working on war orders. The scrap metal market is dull and business quiet. Prices of copper and brass scrap are easier but heavy melting steel and cast iron scrap are firmer at a slight advance in prices. The price of grade "A" spelter has been fixed by the War Industries Board. Apart from this there has been no development of particular importance in the non-ferrous metal markets. Tin continues very scarce at nominal quotations, while the copper market is a routine affair. Prices of machine shop and mill supplies are keeping very firm and business is good. Some lines are in short supply on account of the raw material situation. The machine tool business is fairly active, the demand being principally for equipment for munitions plants.

TORONTO, Ont., Feb. 5.—The fuel regulations ordering a general closing down of factories and munition plants next Saturday to Monday inclusive will cause considerable loss to the concerns involved, but the situation has become so acute that something must be done. The continuous severe weather has badly handicapped railroad operations and increased the already severe traffic congestion, with the result that the movement of coal from the border has not been sufficient to take care of pressing requirements. It is estimated that in Toronto alone the saving of coal will be about 5,000 tons. The fuel regulations apply to Central Canada, from Fort William, Ont., to Riviere du Loup, Que.

### Steel

Conditions in the steel trade continue unfavorable owing to the severe weather which has prevailed for several weeks. The railways have been badly handicapped by the low temperatures, and the yards are still congested, with the result that shipments are coming in slowly. For this reason there is no improvement in the coke situation, which continues acute, and the shortage is interfering with the manufacture of steel, and relief cannot be expected in this quarter until the supply of coke is materially increased. The cold weather is also interfering with manufacturing operations at the steel plants, restricting production considerably. Adverse operating conditions will likely prevail for the balance of this month. The demand for steel for commercial purposes is showing some improvement, but deliveries have been retarded by the freight congestion. Conditions in the trade in the United States are such that steel is even more difficult to obtain than was the case a few weeks ago. Production of steel has declined on account of the severe weather, but the demand is as insistent as ever. The mills consequently are getting behind on deliveries. The freight embargo and the fact that deliveries are in a chaotic condition is still the main topic of conversation in the steel industry. New business is being held in abeyance until the situation shows signs of clearing. War orders, having first call on the available supply of steel, are consuming a greater part of the material being imported, leaving a comparatively small tonnage for ordinary consumers.

No further statement has been given out regarding the proposed increase in the production of steel in Canada. It is understood that plans are being made to utilize the full capacity of the steel plants and ultimately increase the output when satisfactory arrangements have been made in regard to securing ample supplies of raw materials. Little progress can be made in this direction until the spring, when operating conditions will be more favorable. The labor situation will also have to be investigated, as an increase in supply will be necessary to meet the demand arising out of the new conditions. There has been no official confirmation of the contract which the Canadian Car & Foundry Co. is said to have secured for freighters to be built at Fort William for the U. S. Government. It is reported that the whole of the material for the contract has been arranged for with the U. S. Government, and that construction will commence in May. There have been no price changes announced this week and the market is firm.

Under the new regulations steel plants and foundries will have to close down next week-end, Saturday to Monday inclusive. This will mean that production will be further curtailed for the time being, although it may relieve the situation later. The output of the Nova Scotia Steel & Coal Co., for the fourth quarter, 1917, shows an increase in production of ore and limestone and also finished steel and forgings, but a decline in coal, coke and steel ingots. The following are the figures in tons for the quarter ending Dec. 31:—Coal, 135,273; ore, 36,111; limestone, 19,513; coke, 18,850; pig iron, 21,304; steel ingots, 29,216; finished steel and forgings, 25,199.

The T. Eaton Co. has awarded the contract to the Dominion Bridge Co. for 8,000 tons of structural steel for a mail order department building which is to be erected near the harbor front in this city. This is additional to the contract for 20,000 tons for the retail store at Yonge and College Streets, held in abeyance until after the war. The Dominion Bridge Co. and McGregor & McIntyre, of Toronto, participate jointly in a contract calling for 1,800 tons of steel for a shipbuilding company.

### Pig Iron

The situation in the pig iron market is worse rather than better, conditions not having been improved by the severe weather, which is preventing the free movement of coke to the furnaces. Production has consequently been considerably curtailed and the furnaces are getting behind on their orders. Canadian consumers are buying iron from the United States; among these are included makers of agricultural implements who are buying in limited tonnage for foundry use. The situation across the line shows no improvement, and a number of furnaces are still banked due to lack of coke. The continued cold has done much to counteract the relief which would have resulted from the five-day suspen-

sion order. Foundries and other plants not working on war orders are practically unable to get iron.

### Scrap

The market continues dull, with a small volume of business. The outlook in the trade is still somewhat unsettled, due to conditions in the States, where new regulations are anticipated following a reorganization of the sub-committee on scrap iron of the American Iron and Steel Institute. Prices of copper and brass scraps are a shade weaker, but only the latter have declined in the meantime, new brass cuttings and No. 1 brass turnings being down 1c. Heavy melting steel and machinery cast iron, on the other hand, are firmer, and have advanced $1 a ton. The railway situation is discouraging all attempts to do business, as shipments are constantly being held up for indefinite periods.

### Machine Tools

The machine tool market is fairly active, the demand being principally for equipment for munitions plants, although a few orders have been received by local dealers for machinery for general purposes. The report that a shipbuilding plant will be established at Fort William has created considerable interest in machine tool circles, although no official statement has yet been made The Dominion Shipbuilding Co. is looking around for equipment for its new plant at the foot of Spadina Avenue. This concern will participate in the contracts for ships under the new Government scheme. In the States there is great activity in the machine tool trade, which is affecting deliveries in equipment destined for Canada.

### Supplies

Business in machine shop and mill supplies continues brisk, due principally to the activity in the munitions industry. Prices are very firm, with an upward tendency, due to the lack of raw materials, which is also creating a shortage of a number of lines, particularly on those imported from the States. Dealers have to place orders considerably ahead to ensure getting the goods when required.

### Metals

The non-ferrous metal markets are as a rule quiet and devoid of any outstanding feature of interest, except perhaps that the prices of zinc have been fixed by the U. S. Government, although the figure has not yet been given out. The copper market continues a routine affair, while the shortage of tin is still acute, with no relief in sight. Lead is firm, and some scarcity has developed. Antimony is firm, but aluminum is easier. Solders have advanced.

**Copper.**—The copper market is dull, but prices have shown no indication of going below the price fixed by the Government, and it is believed that if there should be an advance in the fixed price there would be very little copper for sale. The production situation is not as satisfactory as is desired, as there is not any enthusiasm for new development or for extension work. It is said by copper men that the rising cost of doing business, including the higher taxes, and the fact that the selling price is limited, has so reduced the probable profit that new capital cannot be attracted to any work in the industry that requires taking more risk than the average in other lines of business. Lake and electrolytic are unchanged at 29c and casting copper at 28c per pound.

**Tin.**—There is no improvement in the tin situation, and the shortage continues acute. In New York the trade is demoralized, as all arrivals and also tin in store are commandeered by the Government. There are no spot supplies of tin available, so no spot market can be quoted. The outlook is not favorable either for lower prices or ample supplies. The situation is thus very uncertain. Prices locally are entirely nominal at 80c per pound.

**Spelter.**—It is reported that the War Industries Board has fixed the price of grade "A" spelter at 12c, but this has not had any effect upon the general market, which has been left to establish its own prices. The demand is light and prices steady at 9½c per pound.

**Lead.**—The market is firm and scarce in the East, due to congestion of traffic. The scarcity is, however, temporary, as an improvement in the railway situation will relieve the tight conditions in the market. The "Trust" price is unchanged at 6.75c New York. Lead is quoted locally at 8¾c per pound.

**Antimony.**—The market is quiet and business dull. Antimony is unchanged at 18c per pound.

**Aluminum.**—The market is very dull, there being more buyers than sellers. Aluminum is quoted locally at 60c per pound.

**Solders.**—Prices of solders have advanced on account of the tin situation, guaranteed being quoted at 44¼c and strictly at 40½c per pound.

### CANADIAN GOVERNMENT PURCHASING COMMISSION

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

## Sydney

SYDNEY, N.S., Jan. 31.—The settlement of the wage disagreement between the operators in the Sydney district and the A. M. W. of N. S. is still in abeyance pending the result of negotiations between the men and the committee sent to Cape Breton by the Minister of Labor, namely, Senator Robertson and Mr. J. C. Watters. An amicable arrangement is, however, looked for, and there is not any likelihood of a stoppage of work.

Outputs recovered somewhat towards the end of the month, helped by a spell of fine weather. The production of the Dominion Coal Company's mines in January reached 270,000 tons, comparing with 236,000 tons in December, and with 318,000 tons in January, 1917.

### Disasters Reduce Output

Another disastrous mine explosion is to be recorded. The Allan shaft mine of the Acadia Coal Co. exploded at 5.30 p.m. on Jan. 23. Nine men escaped, but the remainder of the men down the pit, to the number of 88, lost their lives. About half the bodies still are unrecovered, and the operation of restoring the mine has been hampered by heavy falls of coal and by the rising of the mine water, due to breakage of the pipes and stoppage of the electric pumps. No reliable explanation of the cause of the disaster can be given until full exploration of the workings is possible, but from indications observed it is thought the proximate cause of the explosion was a "bad shot," probably aided by dust. The Allan shaft is sunk on the Ford seam, which attains a thickness of 40 feet, and which like all the Pictou seams is very gaseous. Although the Ford seam is unusually thick, it is not as stated in all the Canadian newspapers, the "largest coal seam in the world." There are much thicker seams in America, and very much thicker seams in China.

The Ford seam has been the scene of numerous fires and explosions, and not far from the present disaster an explosion occurred in 1880 which caused the death of 44 men. The most recent explosion has caused the second greatest loss of life in mine explosions in Nova Scotia, and is greater than the Waterford explosion of last July, in which 65 men perished.

The Acadia Coal Co. also have a fire in the Albion mines, which has necessitated the closing of that colliery, and this company now has only one colliery in operation. As a result the coal shortage will be still further increased, and the future output of coal in the province will be decreased, not only by the immediate loss of the workings affected by the explosion and the fire, but by the loss of the productive labor of the 88 men killed. It may be pointed out that the combined loss of life in the Waterford and the Allan shaft explosions represents the loss of productive labor equivalent to 140,000 tons of coal per year and, in the present state of the labor market, this is a permanent reduction of output for the further duration of the war.

A coroner's inquest is in progress on the victims of the disaster, and it is expected that a technical departmental inquiry will be instituted by the Nova Scotia Department of Mines.

## Washington

WASHINGTON, Feb. 2.—Dr. Garfield's coastle fuel order now seems in a fair way to be repealed. The order which has closed down thousands of manufacturing plants in the United States has been the object of such persistent protest that it now appears that it will be revoked.

Fuel Administrator Garfield and Director General of Railroads McAdoo have held several conferences on the matter and have issued a public statement indicating that they are about to repeal the order. Public protest is not the reason which will be given officially for the withdrawal of the order, when it comes, however. Both McAdoo and Garfield have declared that the effects of the order have been so satisfactory that it will not be necessary to continue it longer.

### Fuel Order Improves Situation

It is generally admitted that the fuel and transportation situation in the United States is much better to-day than it has been for more than a month, and this in the face of the fact that weather conditions have been more severe during the past three weeks than they have been for several years. Coal is now moving to the industrial centers with greater freedom and freight—priority freight—which has been piled in warehouses is beginning to move. This condition is due partly to the embargo which Director General McAdoo placed on all non-essential freight on the two big systems in the Eastern States, the Pennsylvania and the Baltimore and Ohio.

Drastic orders concerning the consumption and distribution of coal which have been threatened from the Fuel Administration will not be put into effect if the closing order is revoked. The Canadian coal supply has been the cause of controversy among manufacturers in the United States who have had their supplies cut off. Movements to secure a closing order in Canada have lost their weight and there is little likelihood that they will ever be presented to the Canadian government in the light of present developments.

### Shipbuilding Prospects

The shipping program of the United States is shrinking daily. Difficulties which are arising from time to time make it more and more certain that the original shipbuilding program adopted by the United States will never be accomplished. The labor situation is growing more serious and shipyard workers are becoming more and more scarce.

A total tonnage of three million tons is the estimate of production now most generally accepted by conservative and well informed men in the shipping industry. All estimates above this are now being discounted. It is predicted by old shipbuilders that the fabricated steel [illegible] seriously and that the difficulties which will arise with this failure will cause a considerable shortage in the estimates of the Shipping Board.

Concrete ships are to be experimented with by the United States government. Congress will be asked to make an appropriation to build and test concrete ships. Roy Robinson, a Chicago contractor, who has made a study of the concrete ship, has presented a report to the Senate Commerce Committee which has convinced that body that the plan is not only feasible but sound. They will ask Congress to give the project the proper support in the way of an appropriation.

It is declared that the concrete ship production can greatly increase the tonnage which is now in sight and that production of this type of vessel will be a great deal more rapid than that of either steel or wooden vessels. The cost of these ships is about two-thirds of the cost of a steel or wooden ship.

If the concrete ship proves to be a success it will bring up the problem of ship machinery. Members of the Shipping Board declare that the present program of ship building will not find a shortage in ship machinery, but they declare that if the concrete ship program should be successful, that there would be a serious shortage in the machinery to equip the hulls with.

### Price Fixing Probabilities

The United States is going to be subjected to further price fixing. There is legislation now before the Congress which will give the President the same powers of administration and price fixing over steel, iron, copper, and other commodities which he now has over food and fuel. This legislation which is still in the embryo stage is most likely to meet violent opposition from all quarters. Manufacturing industries, thoroughly aroused over the fuel order which has closed their plants, are protesting that any further granting away of powers will so cripple the industries of the United States that the conduct of the war will be seriously hampered.

The discussion with reference to the creation of the office of Director of Munitions still goes on, and industry in the United States is holding off until some definite action is taken and it can see what the effects of future legislation may be. President Wilson has ordered that all discussion on this matter be quashed but nevertheless the Congress is debating the question. There is little hope that the legislation will ever be passed against the wishes of the Administration.

American railroads will not be under permanent government control unless some future Congress acts upon it. The committees considering legislation for the control of the railroads have insisted that government control of the railroads be only a war measure and have stricken out the provision in the Administration railroad bill which might be construed to mean permanent government control of transportation lines.

## Pittsburgh

PITTSBURGH, Pa., Feb. 2.—New business in iron and steel, except for the placing of orders by the Government, remains practically at a standstill, as transportation conditions have not improved. In a nutshell the situation is that the iron and steel industry is held by an incubus which it can do nothing to throw off and it is simply waiting until warmer weather dispels the incubus.

### Weather Conditions Hold Up Country

Throughout the winter, or since late in November, the weather has been uniformly bad. There has been no particular spell that has been distinctly worse than the worst of previous winters, but the rapid succession of spells of bad weather, now zero temperatures and lower, now heavy snowfalls, has been altogether unprecedented. Illustrating the situation, last Sunday night there were extremely heavy snowfalls in the east, causing the entire annulment of many passenger trains, while at the same time there was a sleet storm in the Connellsville coke region, causing deposits of sleet more than an inch thick, breaking down many telephone and telegraph wires and further curtailing the production and shipment of coke. Incidentally it may be mentioned that Pittsburgh has had its own troubles. Located in the heart aof the greatest coal producing region of the world it has been short of coal, because the railroads could not increase the service and the river coal on which Pittsburgh normally depends to a large extent has been practically altogether shut off since Jan. 3 by the Monongahela river being frozen. The three lower pools of the river are now clear of ice and steamboats are breaking the ice in the fourth pool, with many fourth pool mines all ready to start the moment the pool is cleared. Above Dam No. 5, at Brownsville, there is an ice gorge six miles long and 30 feet high in places, which there is practically no hope of removing. When the ice breaks up and the snows melt in the upper reaches of the Monongahela and Allegheny rivers, which form the Ohio river at Pittsburgh, a record flood is a possibility if not indeed a probability.

In other winters the railroads have had reserve capacity, and periods between spells of bad weather in which they could recover. This winter they had no reserve of power, but were already overtaxed and there has been no mild weather to afford them any opportunity to recover.

The Fuel Administration's plant-closer order covered the five days ended Tuesday, Jan. 22, and the nine Mondays following. It will probably be rescinded after next Monday, largely because it proves so troublesome. No great amount of relief has been afforded, but conditions have not grown as much worse as otherwise would have been the case.

### Light Operations

Steel mills in the Pittsburgh, valley and lake front districts made shipments during January equal to between 50 and 60 per cent. of their capacity. In the past week shipments have been somewhat lighter still. The greatest restriction has been due to the inability of the railroads to move the finished product. Almost the entire territory is plastered with embargoes, and permits to ship commercial steel through the embargoes are now rarely granted, and even when they are secured the time limit sometimes runs out before the necessary cars are secured. If the shipper makes sure of cars before seeking a permit demurrage usually results. Even war steel is not exempt from the embargoes in all cases. The shipments made in January were almost wholly war steel, the commercial steel shipments in the districts referred to probably representing no more than say 10 per cent. of productive capacity.

Production is no longer materially in excess of shipments as the storage capacity of mill warehouses and yards is already taxed. The difficulty in shipping commercial steel is illustrated by the situation in tin plate. This is essentially a war necessity, as it is important to have the greatest amount possible for taking care of the perishable food crops this summer and under direction of the Food Administration the tin plate mills have been striving to operate fully, the steel mills in turn endeavoring to supply them fully with steel. From the railroad viewpoint, however, tin plate is not a war material, hence it has received no preference and the tin plate mills have accumulated very large stocks, some having already been forced to shut down from their warehouse being full. The average storage capacity equals about six weeks of production. In the past week complete data have been assembled showing the destination of tin plate on order for use of the Food Administration which seeks relief from the railroad administration and an order is expected that will enable the tin plate mills to operate in full.

### No Market Demand

There is practically no demand in the open market for pig iron or steel products for commercial purposes. There is practically no enquiry, buyers show no anxiety as to the shipment of material already ordered, and their specifications against current contracts are very light. They are in the grip of the transportation situation the same as are the producers. It is simply a case of everyone waiting until the passage of the weeks brings better weather and, with the aid of the various efforts made to improve railroad conditions, a freer movement of freight.

What will then occur with the makers is anyone's guess. Production of steel will, of course, greatly increase. The consumptive requirements may increase by the same amount, by more, or by less. Upon this depends whether there will be a strong or a weak market when there is a market again. The set prices are generally observed, or rather there would be if there were any business being done. There is relatively little contract business really in force at prices higher than the Government limits. Much of the higher priced material has been shipped, while as to considerable tonnages buyers have simply refused to consider the contracts as obligations, holding that mills revised prices in the past when there was an open market decline and that the decline at the instance of the Government should be similarly regarded.

On Dec. 29, it was announced at Washington that the set prices were continued to Mar. 31, with prospect of revision by that date. A month has passed and only two months remain, but there is no clear idea of what is likely to occur. March and October are traditionally the months of heaviest production of both pig iron and steel, because the weather in those months is exceptionally favorable. There may be such a burst of production as will cause the market to break. There have been rumors of legislation by Mar. 31, empowering the Government to fix iron and steel prices, and that would be different from the present arrangement, which after all is technically only a voluntary agreement. The set prices are extremely high, more than double the average prices realized during the ten years ended with 1913, while on the other hand costs are very high because everything is high, and at the present time they are exceptionally high because operations are so irregular. One of the possibilities is that Washington will conclude to defer attacking the matter of steel prices in order to allow the industry an opportunity to strike its gait again.

## New York

NEW YORK, Feb. 2.—Current domestic orders for rolled steel products are not large but would be much heavier if the steel mills were willing to acept all the business that is offered. In the last week, several large producers have returned orders and specifications sent to them by anxious buyers because under present conditions the mills can do little more than fill Government contracts. They are making small headway against unfilled commercial orders carried over from last year.

Traffic conditions are still deplorable and lack of an adequate supply of fuel and steel is keeping many manufacturing plants from operating as much as 75 per cent. of capacity. Steel producers, taking the industry as a whole, are turning out ingots at less than 50 per cent. of capacity. A few finishing mills working exclusively upon urgent Government orders are operating 75 per cent. of capacity but most of the finishing plants are still unable to produce even 50 per cent. of capacity.

In the last few days, the Army and Navy Departments have placed liberal orders for structural steel and for wire products, immediately following the distribution of specifications against orders for ship plates and shapes by the Emergency Fleet Corporation. The Ordnance Department has placed additional orders for shells, detonators, fuses, hand grenades and shell accessories among manufacturers in various parts of the country. In turn, these manufacturers have come into the market for machinery and machine tools. Ship builders, also have placed supplementary orders for shop equipment.

Wire drawers have been allotted orders for 20,000 kegs of wire nails by the sub-committee of the Iron & Steel Institute on behalf of the Quartermaster's Department of the Army for export to France. One half of the order was given to the American Steel & Wire Co. Orders for about 15,000 kegs of nails were also distributed for domestic shipment, 5,000 kegs of which are for the Government nitrate plant near Sheffield, Ala. A smaller order calls for shipment to the Panama Canal zone. The Navy Department which continues to place orders independently of the Iron & Steel Institute, requires 20,000 kegs of nails for the powder plant at Charlestown West, Va., one half of which will also be furnished by the largest interest but only 1,500 kegs were shipped this week by all wire drawers.

In structural work interest was mainly centered in the distribution of orders for upward of 20,000 tons of shapes for military buildings in France, most of which went to independent interest. The McClintic Marshall Construction Co. has been awarded a contract for 18,000 tons for 500 hangers to be constructed in France and orders were also placed for 3,000 tons of shapes for six warehouses to be built in France. The other military buildings to be constructed in France will require 25,000 tons of steel and all of the tonnage that is not given to independent shops will be taken by the American Bridge Co. in accordance with an agreement with the Government.

One interesting development is the placing of a contract for 8,000 tons of structural shapes with the Bethlehem Steel Co. for a mail order building for the T. Eaton Co., Ltd., Toronto, Ont. The general steel fabricating contract went to the Dominion Bridge Co. It will be recalled that the large department store to be constructed by the same interest at Toronto, some time since called for 22,000 tons of steel shapes, but this has been held in abeyance. Another Canadian inquiry worthy of note is for 200 line pipe for the province of British Columbia.

Bids have been asked by the Navy Department on tools for machine shops at naval airplane stations in this country as well as in Europe and the Pennsylvania R.R. has resumed the buying of machinery for the American railroad en-

gineers in France. The Gotham Manufacturing Co., Providence, that is manufacturing [illegible] hand grenades, and the Metropolitan Engineering Co., of Brooklyn, that has an order for 1,100,000 trench mortar shells, are buying shop equipment.

### FACTORIES WILL CLOSE FOR THREE DAYS

ON the recommendation of C. A. Magrath, Canadian Fuel Controller, the Cabinet on Monday night passed an order in Council at Ottawa suspending the operation of manufacturing plants for three days, Feb. 9, 10 and 11. The only exceptions are plants which must be continuously operated seven days of the week to avoid serious injury to the manufactured products, plants manufacturing perishable foods or foods for immediate consumption, and plants devoted to the publication of daily newspapers. The order applies to all business and professional offices, warehouses, wholesale and retail stores. For the purpose of selling food only, stores may remain open from [illegible] o'clock (noon) February 9 and 11. The regulations do not apply to the heating of restaurants, hotels or places where meals are regularly served.

The regulations do not apply to Western Canada nor to the Maritime Provinces. The order, as passed, will appear to all of Ontario and Quebec from Fort William on the west to Riviere du Loup on the east. It is understood that it was the intention to pass this order last week, but it was held up owing to doubt as to further action in the United States and the possibility of a discontinuance of their order. Mr. Magrath, who is in Washington, is in close consultation with the American authorities, and is co-operating with them in every possible manner to meet the present situation. This recommendation was decided upon by him as best for the present, although further orders by him along the same lines may be issued later if necessary.

### NOVA SCOTIA OUTPUT

THE output of the Nova Scotia Steel and Coal Company for the three months to December 31 compares with production of the previous quarter as follows:

| | Dec. 31, 1917 | Sept. 30, 1917. |
|---|---|---|
| Coal, tons | 135,272 | 139,795 |
| Ore | 36,111 | 7,174 |
| Limestone | 19,513 | 17,069 |
| Coke | 18,870 | 25,268 |
| Pig iron | 21,204 | 21,874 |
| Steel ingots | 29,216 | 30,845 |
| Finished steel and forgings | 25,199 | 22,657 |

Kingston, Ont.—The City Council has decided to submit a by-law to the people for the purpose of raising by debentures $60,000 for the building of a public wharf.

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE—Valparaiso, British Consul General.

COLOMBIA—Bogota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Bahia, British Consul. Rio de Janeiro, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

### CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian.

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris. Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address, Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol. Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

### CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian. R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum, Grubbegd No. 4 Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

### CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England. Cable address, Dominion, London.

## The A. R. Williams Machinery Co., Limited

**64-66 Front Street West, TORONTO**

---

## *For Rapid Production and Accurate Work*

USE THE

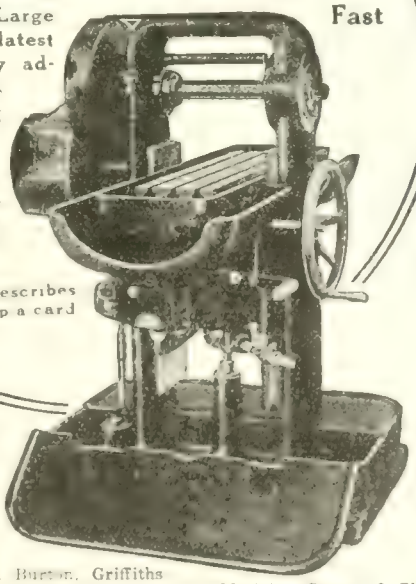
# "BRIGGS"

**The Briggs Miller handles work no other machine of its size can touch.** It is a manufacturing machine. On account of its rigid construction it will produce accurate work when running at a high rate of speed and feed.

**The Base Tank and Large Gear Pump is the latest addition to its many advantages.** Tank holds 20 gallons of cutting lubricant

Pump never requires priming and will deliver ten gallons per minute to the cutters, keeping them cool when run at very high speed.

**Fast**



Our booklet describes fully. Drop a card for it.

# NOSING DIES

## *For All Sizes of Shells*

Recently we told in this space of a Nosing Die in use in our own shops which had nosed 35,000 shells, and was still working. This die is still in use, and doing good work.

We now publish the following letter from one of our customers as a further proof of the long life of our CHILLED IRON NOSING DIES.

Messrs. March & Henthorn,
Belleville, Ont.

Gentlemen:—

We have been using your shrunk and [illegible] for some months past and they have given us better satisfaction than anything we have yet [illegible] for the purpose for which we are using them, having nosed nearly 10,000 shells and to all appearances [illegible] as good as ever and no doubt will [illegible] more.

We would say the [illegible] is an expensive problem for us, as we know of nothing, at several times the price, which will give us the same satisfaction.

Yours truly,

[illegible]

We make these Chilled Iron Nosing Dies for the various sizes of Shrapnel and High Explosive Shells, and also for the .75 Millimeter French Shell.

We also make Chilled Iron Sleeves for Forging Billets for the 75 Millimeter Shells.

## ENGINEERING

Trenton, N.S. — A fire at the Nova Scotia Steel & Coal Co's plant here did about $4,000 damage.

**Montreal, Que.** — Fire has destroyed the plant of the St. Lawrence Welding Co., 138 Inspector street.

**Quebec, Que.**—Price Brothers & Co., Quebec, contemplate the erection of a $30,000 pulp and paper mill on the River Batiscan, near St. Narcisse.

**Toronto, Ont.**—The Turnbull Elevator Co., has been given a building permit to erect a one storey brick factory at 251 Richmond street to cost $20,000.

**Toronto, Ont.**—Canadian Aeroplanes Ltd., have a building permit for constructing two sets of brick dry kilns on Dufferin street near Lappin avenue to cost $9,500.

**Guelph, Ont.**—Damage to the extent of about $3,500 was done by fire, smoke and water at the building owned by the Light and Heat Commission on Huskisson Street on Jan. 30. The loss is covered by insurance.

New Ross, N.S.—The mill and all the equipment of the Nova Scotia Manganese Co. at New Ross was completely destroyed by fire on Jan. 26. The loss cannot be replaced with less than $100,000 and there was only a few thousand dollars insurance.

Prince Rupert, B.C.—W. P. Hinton who was here recently, says that the Grand Trunk Pacific will spend $250,000 in Prince Rupert this year on a brick railway station to meet all requirements for ten years; machine shops and round house at Cameron Cove, and a 1,000-foot wharf.

**Toronto, Ont.**—The Toronto Laundry Machine Company's plant was badly gutted by fire on Tuesday morning. The damage is estimated at $100.000 on the building and machinery, which is covered by insurance. The fire was caused by a resin tank boiling over in the shell-filling room.

**Toronto, Ont.**—The Liederkranz Club property on Richmond Street west has been sold to the Turnbull Elevator Co. for the amount of the assessment of the land and building, $40.000. The property has a frontage of 106 feet and is 160 feet in depth. Purchasers will erect a machine shop on that part of the property not occupied by the German Club premises.

Nelson, B.C. — The Waneta Power Co's big water-power plant on the Pend l'Orelle River, south of Nelson, is nearing completion. Preliminary construction work has been in progress for some years, though the company has but recently been incorporated, with a capital of $1,500,000. Power will be supplied to industries of both sides of the international border.

**Hamilton, Ont.** — The local Hydro Board has decided to reduce the power consumption here by the drastic method of cutting off non-essential industries one day a week. Hamilton is about 1,500 kilowatts short of its requirements, and it was thought that by cutting off certain industries rotation for one day a week this could be made up, and munitions plants and food-producing concerns could keep going without interruption. Several times of late all plants depending on Hydro have been cut off owing to this city having exceeded its limit, and it was thought this would be the most effective and most satisfactory way of meeting the situation.

**Cornwall, Ont.**—The St. Lawrence Power Co's. plant at the Sheiks Islands dam, which supplies electric power to several industries in Cornwall, is completely out of commission as a result of the high water. All local plants are shut down and this may last until the water recedes and repairs can be made. The water rose nine feet above the floor in the power house, putting the generators and transformers completely under its surface. Officials of the company stated that it would take at least a week to dry out their machinery and have it ready for action after the power house is cleared of water. The Stormont Electric Light & Power Co is doing all in its power to relieve the lighting situation in town by transferring their power wherever possible.

## MUNICIPAL

**Perth, Ont.**—The Town Council will ask the Provincial Legislature for a bill to confirm a by-law in connection with a bonus of $25,000 by way of a loan to the Perth Carpet Co.

**Niagara Falls, Ont.**—The Hydro Commissioners of Ontario have agreed to let the City of Niagara Falls tap the new pipe which is being laid with a 24-inch main, which will give this city all the water it needs for many years to come. At the same time this will only be a temporary arrangement, as the city is negotiating with the Hydro for a permanent supply from the Power Canal being constructed.

**Niagara Falls, Ont.**—Work is already well started upon the new pipe which is to supply 50.000 more horse-power for the Hydro. The pipe, which is 13½ feet in diameter, is to be run through Queen Victoria Niagara Falls Park. The work on the Chippawa-Queenston Hydro Canal is proceeding in spite of the severe weather, though it is exceedingly difficult to get men to stay on the job. As soon as weather conditions prove more favorable the Hydro engineers will put a new impetus on the job. The railway along the power canal is progressing and preparations are being made for dredging.

## GENERAL

**Pictou, N.S.**—The Atlantic Milling Co. may build a mill here.

**Vancouver, B.C.**—The Sidney Rubber Roofing Co., Sidney, Vancouver Island, contemplate the erection of a $125,000 factory.

**Quebec, Que.**—Work on the extraction of coal from a mine discovered on the cliff near Levis has started. It is not yet established whether Quebec only has a stray deposit of coal or whether it is a far-stretching vein.

**St. Thomas, Ont.**—A valuable peat-bog has been discovered on the farm of D. A. Campbell, in Southwood Township, a few miles west of St. Thomas. This bog is about six acres in extent, and the peat is an excellent quality and burns readily in grate and stove.

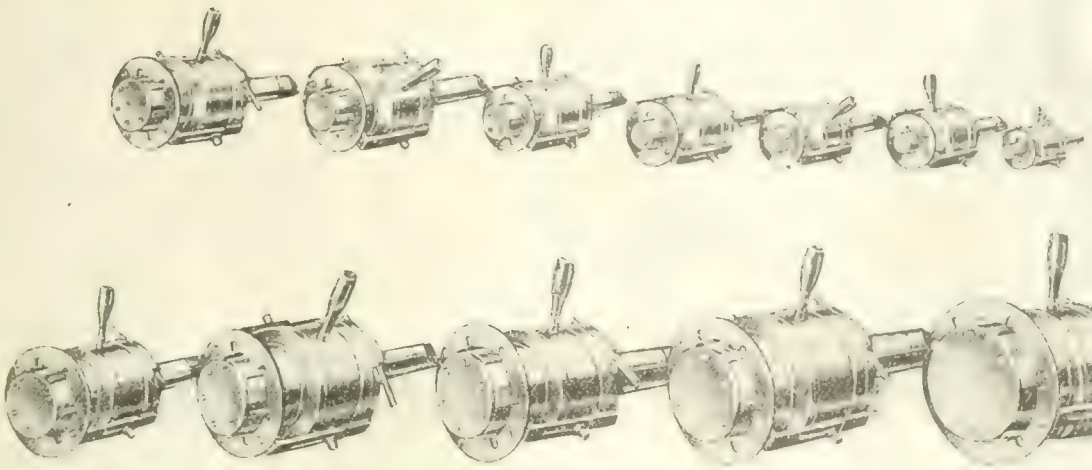
## BUILDINGS

**Toronto, Ont.**—A building permit has been issued to the Adams Furniture Co. to construct on elevator shaft in warehouse at 227 Victoria street, to cost $2,000.

**Ottawa, Ont.**—The Dominion Government purposes to erect in Ottawa a large office building. It will be put up in the coming year if plans now under way materialize. It is undecided yet whether the site will be on Wellington Street, where the Government owns all the property on the north side to Pooley's Bridge, or elsewhere. The plans are now being considered by the authorities of the Department of Public Works, under Hon. F. B. Carvell. The new building would cost more than a million dollars.

**Toronto, Ont.**—The Finance Committee of the Board of Education, at a special sitting held recently for the purpose of considering the estimates prepared by the several committees and officials, sent forward to the board without recommendation the Property Committee's request that $150,000 be included in the estimates for the building of a new Rose Avenue School. Previous appropriations will provide for the Glenholme avenue school, which is to cost $100,000, and Glengrove avenue school, which is to cost $70,000. The committee also included in the estimates $1,050 to equip three new household science centres, and a similar amount to equip three new manual training centres.

# GEOMETRIC TAPS



# FOR U.S.

## *SIZES ¾" TO 6"—AT A U.S. ARSENAL*

THIS illustrates only one of the groups of Geometric Collapsing Taps that have gone into United States Arsenals and Navy Yards to bear out the reputation that attaches to all Geometric Thread Cutting Tools.

These taps are equipped with the roughing and finishing attachment, a feature of Geometric Taps that are required for close work.

A micrometer scale adjusts them for a tight or loose thread. Because of the adjustable feature, Geometric Taps always produce accurate threads, no matter how often the chasers have been ground.

When ground beyond further use, the chasers may be replaced, while the tap remains as good as new.

Chasers recede automatically when the required depth of thread is reached.

Geometric Collapsing Taps can be fitted to Screw Machine or Turret Lathe, also live spindle.

Why not put your tapping proposition up to a Geometric?

**THE GEOMETRIC TOOL COMPANY**
**NEW HAVEN CONNECTICUT**

***Canadian Agents:***

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

# PERSONAL

Gordon Grant formerly chief engineer of the National Transcontinental Railway, has been appointed expert adviser to the Minister of Railways.

A. E. Warren, general manager of the Canadian Northern Railway, has been appointed to the Government service as Deputy Minister of Railways.

William Allan Foley, who for some years was superintendent for Goldie & McCulloch Co., Galt, Ont., died in that city on Jan. 27, in his 75th year. The deceased had lived in Galt over fifty years.

Thomas Robb, manager and secretary of the Shipping Federation of Canada, has been appointed chairman of the commission which will investigate pilotage conditions at Halifax and other Lower Province ports.

**William R. McCulla** is now affiliated with the aircraft division of the Willys-Overland Co., at Elmira, N. Y., and Toronto, Ont., having resigned as aircraft motor engineer of the Packard Motor Car Co., Detroit.

**R. W. Williamson**, assistant superintendent of the munition plant at the Renfrew Machinery Co's factory at Renfrew, Ont., has resigned to take up a position with the T. A. Gillespie Co., Perth Amboy, N.J., under the Ordnance Department of the United States Government.

**Arthur B. Sweezey**, who has been attached to the New York office of the Cunard Line for more than twenty-six years, has left for Vancouver to establish an office in that city for the company. This is the first of a series of branch offices which the Cunard Co. will establish in various parts of the world.

**Marcel Beullac**, engineer of the Dominion Bridge Co., Lachine, Que., died suddenly on Jan. 27, at the age of forty-six years. Mr. Beullac was graduated with honors from Laval in 1897, and had become prominent in his profession. He was an ex-president of the Veterans of Land and Sea, and fought with the French army in the present war.

**Thomas F. Hodgson**, sales representative of the Steel Company of Canada, Toronto office, has been granted leave of absence for two months on account of ill-health. Mr. Hodgson has gone to Jacksonville, Fla. Before leaving for the South he was presented with a purse of gold by his friends, the presentation being made by Frank E. Barchard, secretary-treasurer of Ward 6 Liberal-Conservative Association, of which Mr. Hodgson is president.

**William A. Noble**, chief engineer at the Normal School, Toronto, for the past twelve years, died suddenly on Monday morning at the home of his brother, Trustee Dr. John Noble, 219 Carlton Street. A few days ago he was seized with la grippe, which resulted in complications. The late Mr. Noble, who was born in Peel County 57 years ago, had spent the last twenty years in Toronto. He was a member of the Masonic order and a member of L. O. L. No. 140. The body will be interred at Mono Centre.

**Edward R. Stettinius**, a member of the firm of J. P. Morgan & Co., New York, has been appointed surveyor-general of supplies for the United States army. Mr. Stettinius was president of the Diamond Match Co., Chicago. When J. P. Morgan & Co., on January 15, 1915, became purchasing agents for the allies in the United States, they retained Mr. Stettinius in an advisory capacity and later admitted him as a partner because of his ability. Mr. Stettinius was born in St. Louis in 1865, and was at one time connected with the Stirling Co. and the Babcock & Wilcox Co., of Chicago.

**A. D. Armitage** has been appointed president of the Whitman & Barnes Mfg. Co., Akron, Ohio, and St. Catherines, Ont., in succession to A. B. Rinehart. Mr. Armitage has been continuously connected with the company 25 years at its three factories and offices in Akron, Chicago and St. Catherines, Ont. He started as mechanic in the Akron factory Sept. 1, 1892, became purchasing agent in 1900, was transferred to the Chicago factory in 1902 and made superintendent of that plant in 1904. In 1908 the board of directors elected him general manager of the three factories and manager of sales for Canada. At the annual meeting in 1915 he was elected vice-president and manager of the Chicago and Canadian factories with charge of sales at those offices. His various official positions at the three factories and offices during his period of connection with the company particularly fit him for the office of president.

# TRADE GOSSIP

**Port Colborne, Ont.**—Town Council contemplate the installation of a waterworks plant and pump equipment.

**Norwich, Ont.**—Town Council propose enlarging the pump house and installing additional pump at a cost of $4,000. Engineer, F. J. Ure, C.E., Woodstock.

**Regina, Sask.**—The T. Eaton Co., of Toronto, will build a warehouse here at a cost of $350,000. The architects are Woodman & Cubbidge of Winnipeg.

**Kitchener Customs.**—The Customs returns for the month of January amounted to $81,566,700, a decrease of $22,-047.30 in the collections for the same month last year.

**Montreal, Que.**—An influential deputation from Sault Ste. Marie, Ont., came to the city to interview F. W. Clergue, president of the Universal Transmissions, Ltd., regarding the construction of a shipbuilding yard and drydock at the Soo.

**The Empire Waterworks Supply Co.**, of Winnipeg, has been awarded contracts from the Greater Winnipeg Water District for three 24-inch Rensselar gate-valves, all of the automatic air cluster valves and sluice gates, the latter being Coldwell and Wilcox.

**Steamer Bermudian Sunk.**—Word has come to the Marine Department at Ottawa that the steamer Bermudian, taken over by the Admiralty from the Canada Steamship lines, has sunk in Alexandria Harbor in the Mediterranean. It was due to an accident. The ship is to be salved.

**U.S. Authorizes Increase in Coal Rates to Canada.**—Filing of tariffs providing for increase of fifteen cents a ton on coal from points in the United States to Canada was authorized on Jan. 29 by the Interstate Commerce Commission. This follows the action of the Canadian Public Utilities Commission in approving such an increase.

**Turpentine Controlled in England.**—Turpentine has now been placed under British Government control. Licenses are required for all dealings exceeding an aggregate of five gallons during any one calendar month. The order covers all substitutes capable of being used as a substitute for spirits of turpentine except motor spirit and benzine.

**Vancouver, B.C.**—The Lyall Shipyards at North Vancouver are beginning to look forward to another launching, the present indications being that the furthest advanced of the Munitions Board wooden steamers will be ready for the water within the next three weeks. The yard is getting ready to fit tail shafts, which are expected to arrive from the East shortly.

**U.S. Government Buys Platinum.**—A tentative price of $90 an ounce has been set by the U.S. Government for the purchase of 21,000 ounces of platinum recently imported from Russia. Bankers in Petrograd who financed the collection of the metal will be allowed to produce proof of the expense incurred if they think a higher payment should be made.

**Probe Pilotage System.**—The Minister of Marine and Fisheries will, in the course of a few days, create a commission to investigate the pilotage systems in operation at the port of Halifax, and other important ports. In view of the recent disaster at the port of Halifax, the commission will first direct the inquiry into the pilotage system and its operation at that port.

**Vancouver, B.C.**—Confirmation that the British-Canadian Lumber Corporation has entered into an arrangement with the Masset Timber Co. to log for high grade aeroplane spruce on the limits of the former company on Masset Inlet, was admitted by J. T. T. Paxton, receiver and manager of the British-Canadian Lumber Corporation.

**Canadian Firms Doing Business With the U.S.**—The United States War Trade Board, 1435 K. Street, Washington, D.C., invites Canadian firms to communicate direct with the Board so that such firms doing an import or export business with the United States may have their names and addresses placed on the mailing list of the War Trade Board to receive direct, copies of all publications issued by that Board.

**U.S. Zinc Prices Fixed.**—A report from Washington says that zinc prices have been agreed upon by representa-

# Oster Bull-Dog Die Stocks

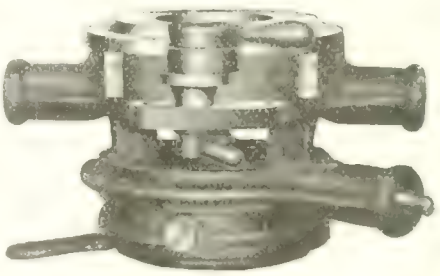
1. Self-locking Dies
2. Self-locking Guides
3. No Resetting
4. No loose bushings
5. No small parts

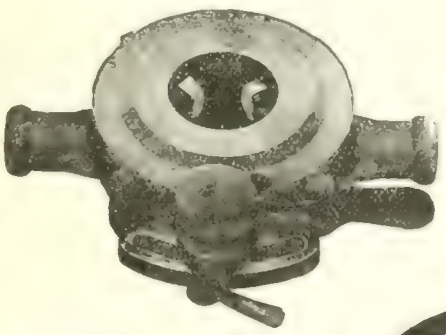
In Oster Bull-Dog Die Stocks you have an adjustable stock without small parts to lose or get out of order, and with nothing to break in use. Levers are made of solid drop-forged steel, and one continuous bolt with a locking handle completes the whole.

To set die stock for threading, simply move both levers to the right. Open or close the dies by one movement of the releasing lever. Change from one size to another, or set for over or under size by movement of the adjusting lever.

Other exclusive Oster ... features better the work and save much time. Write:

**Positive Lever Lock "The Bull-Dog Grip Never Slips"**





Oster Bull-Dog Die Stocks in Nos. 101 to 105, as shown above, thread from ⅛" to 3" pipe.

Aikenhead's

taxes of the Government and the municipality, and will be assessed upon. It is expected that the Government manufactures of basic iron, copper and steel, the zinc producers said such action would stabilize the market and increase the output.

Dominion Customs Receipts.—Customs receipts for the ten months of the fiscal year ending Jan. 31 totalled $176,562,... as compared with $157,...,410 over the same period last year, when they amounted to $119,...,796. A decrease of $2,637,571 in receipts for the month of January this year as against January, 1917, is shown by the monthly customs statements. Last year receipts for January totalled $12,936,314, while this year they amounted to $10,298,742.

Halifax, N.S.—Another shipbuilding plant has been established at Meteghan River by the R. H. Rowes Construction Co., of Boston and New York. The president of the company is George D. Morecroft. A lease for term of years has been taken of the shipyards of the late James Cosman at the mouth of the Meteghan River. Already, mills and pattern shops, equipped with the latest improved shipbuilding machinery, have been erected and are now working.

**Niagara Falls, Ont.**—The Water Commissioner of Niagara Falls, Mayor Stephens, C. C. Cole, and T. E. Ferris, have interviewed heads of the Hydro-Electric with reference to making plans for new source of water supply for Niagara Falls, thus doing away with difficulties met with every Winter by ice blocking the intake on the river. One plan proposed is to give Niagara Falls a supply of water from the new Chippawa power canal, now under course of construction.

**Cunard, Anchor and Donaldson Lines Unite.**—Announcement of a steamship merger that may mean a great deal to the development of British and Canadian after-the-war trade was made last week at the Montreal office of the Cunard Line. The Cunard, Anchor and the Anchor-Donaldson lines were joined under one management on Jan. 1. They will be operated, so far as their Canadian business is concerned, under the supervision of the Robert Reford Co. instead of through American offices, as heretofore. Joint offices have been established in Winnipeg and Vancouver.

**Demand for Stone-Crushing Machinery in New Zealand.**—The Thames County Council has authorized the investment of $24,332 in quarry equipment and appliances for the production of crushed stone to be used in the development of better roads in that country. Communications addressed to the chairman of the County Council at Thames, New Zealand, will reach the right parties in connection with this development. This is probably the beginning of many other similar undertakings in different parts of New Zealand, for there seems to be a determined move in favor of better roads for the country.

**Chatham, Ont.**—The Chatham Public Utilities Commission is considering the advisability of asking local manufacturers using Hydro power to operate their plants on night and day shifts in such a manner as to prevent any heavy peak loads at certain hours. The consumption of power in Chatham is considerably in excess of the allotment, resulting in the street lights being turned off at night and industries operating at night forced to economize. The normal consumption is 1,132 horse-power, while the city under the new orders is allotted 540 horse-power during the day and 940 at night.

**Building New Sub Fighters.**—A report from Washington states that new submarine fighters of a powerful type are about to be turned out in the United States in large numbers. Contracts for the new craft have been placed with the Ford Motor Co., of Detroit, Mich. All parts of the ships except the engines are to be fabricated in Detroit and the parts shipped to to the seaboard, where they will be assembled. Changes in the Ford plant to permit the handling of the work have progressed so swiftly, Mr. Daniels said, that deliveries on the contracts during the coming summer are assured.

**Canadian Car and Foundry Co. to Build Ships.**—It is reported that the Canadian Car and Foundry Co. has closed a contract for building steel ships at Fort William, Ont., for the United States Government to the value of $10,000,000. It is understood that tenders are to be called shortly for the construction of a new building, 220 by 200 feet, in which the boats will be built, and a marine railway and slip will also be built for launching the boats as they come from the works. The whole of the material for the contract has been arranged for with the United States Government, and shipbuilding will commence in May.

**May Build Foreign Ships at Coast.**—Word has been received in Vancouver, B.C., that the Dominion Government will use its endeavors to have the restrictions removed against the building of ships in British Columbia for foreign registry. While nothing official has been given out, it is pretty generally understood by the firm interested in the securing of foreign contracts that their case is receiving more than sympathetic consideration at Ottawa. In the event of the Imperial authorities taking the ban off the construction of ships for foreign contracts, it is stated that there are contracts for several French ships that can be signed in Vancouver forthwith and construction proceeded with immediately.

**Trade Journals Exhibit at Newark.**—An exhibit of trade journals is being held in the Newark Library Building, Newark, N.J. from Jan. 10 to Feb. 12 inclusive. The exhibit will include twelve hundred of the larger and more important trade journals published in the United States and Canada covering every known industry. They are so displayed that each magazine may easily be seen and handled by visitors. The journals were first collected by Miss Adelaide Hasse, chief of the Economics Division, New York Public Library, and shown at the annual convention of the American Library Association at Louisville, June, 1917. They were borrowed by the Newark Library and Museum and are being exhibited as described in the art gallery of the museum in the Library building.

**New Patents Issued.**—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained: Alex. Lamblin & Horace P. Cousin, radiators for motors of dirigibles and aeroplanes; James L. & Ernest Scott, friction driven drop hammers; Geo. W. Berry, constructing lid hinges for sheet metal receptacles; Theodore M. Coressy, auxiliary air admission devices for internal combustion engines; Cecil M. Dyer, apparatus for use in the carburetion of hydro-carbon liquids; George A. Guess, processes of electrolytically separating nickel from copper; B. H. Montgomery & J. B. Dingwall, hose reel; Wilard Chipman, speed recorder; Charles Haythorpe, the purification of water.

**Plan to Relieve Power Situation.**—The question of the shortage of electrical energy, particularly in the Niagara power zone, was discussed at great length at a meeting of the Ontario Municipal Electric Association at the City Hall, Toronto, on Jan. 30. It became clear that the two main obstacles to a continuous supply of power were the ice troubles in the Niagara River and the inability of the power companies to prevent breakdowns. If all plants could be operated at full capacity continuously there would be sufficient power available to meet existing demands. In addition to this it was apparent there was a lack of co-operation between the private power corporations and the Hydro Commission. A resolution was carried favoring the appointment of Sir Adam Beck as power controller for Ontario to act with Sir Henry Drayton.

**Vancouver, B.C.**—Messrs. Norman R. Wilson and H. Stainton, the two experts brought from the East by the Fire Underwriters' Association last summer to investigate the efficiency of the city fire department, recommended the purchase of two fire-boats, according to a report made by Fire Chief Carlisle to the civic fire and police committee recently. One of these boats would be for False Creek and one for Burrard Inlet, the former to be placed in service with as little delay as possible. It was recommended by the investigators that the boats be equipped with pumps capable of delivering 5,000 gallons a minute at a pressure of 150 pounds to the square inch, and with machinery to drive them at a speed of not less than twelve miles an hour. A motor-driven watertower for each boat was also advised.

## ILLINOIS TOOL WORKS, CHICAGO, U.S.A.

The Columbus Chain Co. with factories at Columbus, Ohio and Lebanon, Pennsylvania, and the McKinnon Chain Co. manufacturers at Buffalo, New York and St. Catharines, Ont., have been united under the name of the Columbus McKinnon Chain Co. The new company have formed a Canadian organization, known as McKinnon Columbus Chain Ltd., with general offices at St. Catharines, Ont. Besides offering the trade a [illegible] electric welded chain, it is the intention in the near future to manufacture fire welded chain at St. Catharines under supervision of experienced men from the Columbus plant. The new company will therefore be in a position to offer the well known chain of the Columbus company but manufactured in Canada. Until the Canadian plant is in operation orders for fire welded chain will be imported from Columbus, Ohio.

**Smelters Operating at High Efficiency.**—Plants of the Consolidated Mining and Smelting Co. at Trail, B.C., are now operating highly efficiently according to Managing Director J. J. Warren. By the installation of most modern machinery and the prompt adoption of the latest practicable improvements, the company is now able to turn out fully as much metal with its present staff of 1,200 men as with 1,600 several months ago. So that it is able to maintain its output in spite of the heavy reduction in staff due to enlistment in the army; and moreover, a considerable economy is affected by the saving of some $40,000 a month in wages. "The plants of the company have been built primarily to take care of the peace needs of Canada, in the metals it produces; so that war orders are only incidental to the successful operation of the company, and not absolutely essential, as in the case of some corporations. In this connection it is pointed out that the company will be able to continue a steady regular business when there are no more war orders to be obtained."

**Canada Iron Foundries' Situation Improving.**—A substantial increase in sales and earnings in 1917 permitted of a further strengthening of the position of Canada Iron Foundries, Ltd., successor to Canada Iron Corporation, when went into liquidation about four years ago. The reorganized company, in its second annual report, submitted to shareholders at a meeting in Montreal on Feb. 1, reported an increase of 44 per cent. in the year's sales, which make the total for the twelve months ending September 30th last about $2,849,000, against $1,979,933 the previous year. If allowance is made for the change, the foundries' earnings for the year amounting to $528,097, compare with $337,692 in 1916. Including $14,160 earned as interest, discount, etc., the net revenue of the year was $542,257. During the year the company sold its furnace at Midland, Ont., for $325,000 and completed extensive improvements to the plant at Three Rivers, Que. The company did not operate its mines or furnaces owing to prevailing conditions in the trade.

**Power Shortage for Hamilton Industries.**—Unable to secure a sufficient supply of power to meet the demands, the Hamilton Hydro Electric Board has been forced to issue an order that all industries operating by Hydro power, save the manufacturers of munitions and essentials shall close down one day a week until the present situation has been relieved. This action became imperative owing to the inconvenience and losses the manufacturers were suffering by reason of the frequent interruptions in the service resulting from the Ontario Commission shutting off the entire city every time it went over its load limit of 7,500 kilowatts. The shortage of power in Hamilton amounts to about 1,500 kilowatts, and by shutting off one-sixth of the non-essential industries each day the local commission hopes to be able to provide a steady service for the balance. Manufacturers will be given due notice of the days on which they will be expected to shut down, and non-compliance with the order may mean that they will be shut off altogether.

**National Clay Products Association Convention.** — The Canadian National Clay Products' Association, in session at the Prince George Hotel, Toronto, on Jan. 29 decided, after considering the suggestion of Dr. Wilfrid Grenfell that brick dwellings might be erected in Labrador, to render the distinguished missionary every assistance in testing the clays to be found in the far nothern region. Consideration will be given to the establishment in Toronto of a school of ceramics. At present students desiring to study this practical and useful trade are obliged to take their courses at schools of ceramics in different parts of the United States, several of which have well-equipped laboratories. It has been suggested that a laboratory be placed in the Central Technical School and equipped with kiln and machinery. The following officers were elected for the current year: Past President, A. F. Greaves-Walker, Baltimore, Md.; President, Thomas Kennedy, Swansea; Vice-Presidents, Wm. Burgess, Tomorden; Ryland H. New, Hamilton, and G. Angus German, Toronto; Secretary-Treasurer, Gordon C. Keith, Toronto.

## TENDERS

**Halifax, N.S.**—Tenders will be received until Thursday, Feb. 14, 1918, for the reconstruction of steel roof trusses, Drill Hall, Halifax, N.S. Plans and forms of contract can be seen and specification and forms of tender obtained at the offices of the Chief Architect, Department of Public Works, Ottawa, of the Overseer of Dominion Buildings, Post Officer, Montreal; of the Clerk of Works, Postal Station "F," Yonge St., Toronto, and of the Clerk of Works, Halifax, N.S.

**Melbourne, Australia.** — Tenders for the following may be adressed to the Director of Navy Contracts, Navy Office, Melbourne: Supply, delivery and erection at Garden Island, of one (1) 200 horse-power prime mover set of either semi-Diesel type or other heavy oil engine direct coupled to 2-65 K.W. 240 volt D.C. electric generating set. All accessories, tanks and fittings to be supplied by tenderers as per specification. Date of closing June 7, 1918. Tender forms are open for inspection at the Department of Trade and Commerce, Ottawa. File No. 20117.

**Ottawa, Ont.**—Tenders will be received until March 18, 1918, for heating and ventilating equipment required in the reconstruction of the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all materials, tools, appliances, scaffolding, apparatus and labor required for the installation of the heating and ventilating equipment as called for in the plans and specifications. All information can be obtained at the office of the General Contractors, P. Lyall & Sons Construction Co., Ottawa. A set of plans and specifications may be had by depositing an accepted bank cheque for twenty-five ($25.00) dollars made payable to the Honorable the Minister of Public Works, which will be returned if the intending bidder submits a regular bid.

**Ottawa, Ont.**—Tenders will be received until March 18, 1918, for rolled steel casements and bronze covered frames and sash for the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for (a) rolled steel casements; (b) bronze covered frames and sash. Separate tenders to be submitted for "a" and "b." The work included under this contract shall be commenced immediately on the signing of the same, or at such time as may be directed, and be carried out in such a manner as to insure the completion thereof by Sept. 30, 1918. Plans and specifications, and any other information required can be obtained at the office of the General Contractor, P. Lyall & Sons Construction Co., Ottawa.

## MARINE

**Toronto, Ont.**—The second Norwegian freighter which is being built at the Polson Iron Works will be launched on Monday morning. The ice in the bay which is nearly five feet thick will have to be cut away near the ways to permit of the vessel being put in the water.

**Victoria, B.C.**—The name of the wooden steamer, War Tyee, was changed to War Yukon a few days before being launched. The War Yukon will be the first vessel of the Imperial Munitions Board to get her machinery, and will, no doubt, be the first of the twenty-seven under construction to get away to sea. She has reached the stage when she is ready for installation of her engines.

**Vancouver, B.C.**—The steel steamer Alaska, launched from the Coughlan lards on Jan. 19, has been moved to the fitting-out berth and work will be commenced installing the engines and boil-

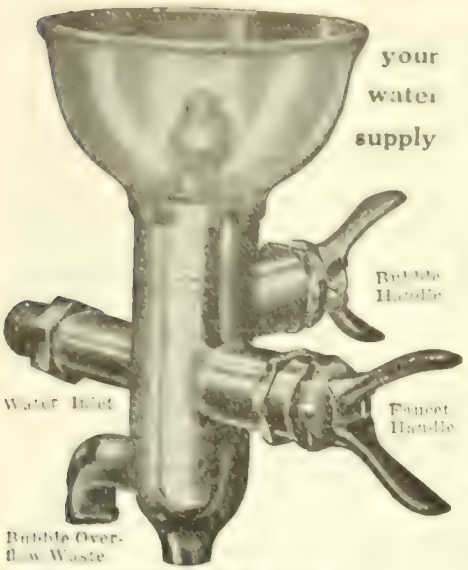
"PURO-FY"

(MADE IN CANADA)



THE American Museum of Safety conferred a Gold Medal Award upon the Puro Sanitary Drinking Fountain at the First International Exposition of Safety and Sanitation.

The Puro Sanitary Drinking Fountain won because it deserves to win. Puro had merits that made it stand head and shoulders above any other drinking apparatus.

**Safe Simple**
**SANITARY Economical**
**Quickly Attached**

These are the qualities that forced the leading safety and sanitary engineers to pick Puro in preference to all others.

No device can be as efficient that does not contain all these qualifications, and Puro was not built for first place. Puro was first.

Don't be satisfied with half way goodness, or make-shift drinking arrangements for your employees.

If the men in your factory must drink, give them a clean drink.

Puro is [illegible] not rust or corrode.

Puro is economical. It allows just the proper amount of cool fresh water to come through the bubbler. No spurting, no overflowing to waste. Puro regulates itself. You can "PURO-FY" in five minutes.

Tell us how many men in your factory and your water pressure in pounds—

We will tell you just what it will cost to "PURO-FY" YOUR WATER SUPPLY.

**Shell Forging Production**

WITHOUT AN EQUAL FOR BOTH FIRST AND SECOND OPERATION PUNCHES.

Comes to you heat-treated and ready for use.

It does not stick to the work.

There are many cases where each punch has turned out over 2,000 shells.

It means more shells, per machine per day.

STEEL OF EVERY DESCRIPTION.

ers. The engines are coming from the East, but the boilers were made at the Coughlan yards. The next vessel to be launched from the yard will be the War Camp, which will be sent down the ways some time this month.

**Victoria, B.C.**—Capt. T. E. Gilmour, of this city has invented a caulking machine. The machine consists of two V-shaped guides which force the oakum under two revolving steel disks, the latter being hammered by compressed air into the seams, a handle to draw and steer the machine along the seams, and eight tension springs to hold the guides in position make up the device. It is claimed that the machine can caulk at the rate of 600 feet per hour.

## INCORPORATIONS

**The Waneta Power Co.** has been incorporated at Victoria, B.C., with a capital of $1,500,000 to take over the business of the Waneta Development Co. of Nelson, B.C.

**The Colonial Shipping Co.** has been incorporated at Victoria, B.C., with a capital of $40,000 to construct and operate vessels of all kinds with head office at Vancouver.

**John Meston & Co.** has been incorporated at Victoria, B.C., with a capital of $10,000 to carry on the business of iron founders and mechanical engineers, etc., at Victoria, B.C.

**The Allan & McKelvie Engineering Co.,** has been incorporated with a capital of $50,000, at Victoria, B.C., to acquire and take over as a going concern the firm of Allan & McKelvie of Vancouver, brass, iron and steel founders, marine and mechanical engineers, etc.

## CONTRACTS

**Toronto, Ont.**—The Dominion Bridge Co. and McGregor & McIntyre have secured a joint contract for 1,800 tons of steel for a shipbuilding concern.

**Toronto, Ont.**—The T. Eaton Co. has awarded the contract to the Dominion Bridge Co. for 8,000 tons of structural steel for a mail order building to be erected near the harbor front.

## BOOK REVIEWS

**Principles of Iron Founding,** by Richand Moldenke, E.M., Ph.D.; 517 pages, 6 x 9 in., illustrated; published by McGraw-Hill Book Co., Inc., New York. Price $4.00 net, postpaid.

Following this is a brief outline of iron metallurgy dealing with the relation of iron to each of the principal elements met with in foundry work, after which chapters V to XIII deal with properties, materials, processes and results, the properties of cast iron being dealt with in 80 pages alone.

To progressive foundrymen in the western hemisphere, the name of

Moldenke is indicative of all that is authentic in iron founding, and this book, which embodies the principles developed by the author during an exceptionally efficient lifetime, is an excellent example of a modern technical treatise. It deals directly and lucidly with the basic principles underlying the best modern foundry practice, and contains just sufficient historical data to make the foundryman realize the dignity of his calling and the dependence of modern civilization on the accomplishments of the moulder and cupola man. The manufacture of iron is traced from ancient times down through the development of it in Europe and latterly in America. The second chapter, dealing with the industrial status of the foundry contains desirable information regarding allied industries and their relation to the foundry—i.e. the status of the foundry in relation to manufacturing enterprise, producers of raw materials, purchasers of castings commerce and finance, exporting and banking; inter-foundry relations; association activities; internal foundry conditions. Chapter III. deals with foundry organization.

The treatment of the various sections is particularly complete, technically accurate, and possesses a readability equalled by few technical works and excelled by none.

## CATALOGUES

**New Catalog of "Beaver" Tools.**—The Borden Co., Warren, Ohio, has just issued its 1918 catalog of "Beaver" easy working die stocks and square-end pipe cutters. This catalog is said to be the finest tool catalog ever issued, and its attractive appearance indicates that no expense has been spared in securing the services of the best artists and printers. This book is printed in two colors, on high grade paper, and illustrates in a complete and artistic manner the complete line of the "Beaver" product. Several new "Beaver" tools are shown for the first time in this catalog—one of the most popular of these being the new No. 3 "Beaver" Junior ratchet die stock, which is built on the unit plan to thread pipe from ⅛ in. to 1 in. inclusive. While this expensive catalog is not intended for general distribution, the Borden Co. will undoubtedly send a copy to any of our readers who will write a letter or card stating that they are interested in "Beaver" tools.

Engineering and Machine Works of Canada Ltd. has been incorporated at Ottawa with a capital of $1,000,000 to take over as a going concern that part of the Jenckes Machine Co's. business heretofore carried on at St. Catherines, Ont.

# Some Applications of Air-operated Machine Tool Equtpment

Staff Article

*The tendency to use specialized equipment when the object is either to produce expense is now thoroughly established among progressive manufacturers and the resume of various applications of compressed air to increase production and save labor forms the accompanying article should serve a helpful purpose in refreshing the minds of many readers.*

IN continuance of an article on air operated mechanism as adapted to machine tool operation, which appeared in our issue of January 3, the following article describes several additional applications, more particularly to shell work:

### Control Valve

Control of the air for pneumatic equipment is generally obtained by the use of some type of three-way valve, as it is necessary to have an efflux for the discharged air and also a passage for the incoming supply. A valve that has been used with considerable success in the main line of an air system is shown in Fig. 1. This valve is attached in such a position that it is within easy reach of the operator. As the purpose of pneumatic equipment in conjunction with machine tools is to facilitate operation and speed up production, it is obvious that the essential factor is rapidity of action, and it is, therefore, important to locate operating valves so as to be conveniently manipulated by the workman when standing in a normal working position. The valve here illustrated is of the revolving disc type, contact being made on two flat surfaces. The cover B is secured to the body A and made airtight by the gasket shown. To prevent air leakage around the stem the gland C is provided, packed as indicated at D. The air supply enters at G, above the disc E of the valve, thus maintaining a constant pressure and keeping the valve to its seat. Operation of the handle F brings the holes H and I in line for the passage of the air to the pipe line. By providing additional openings in the base more than one line can be supplied. The movement of the valve spindle is regulated by a screw in the body of the valve, a suitable slot being cut in the side of the disc.

### Quick Return for Carriage

In order that maximum production may be maintained it is necessary to give special attention to the physical requirements of a workman in the performance of his duties. Properly cared for, a machine tool will accomplish as effective work at the close of a day as at the beginning. On the other hand, the man at the machine will invariably feel the strain of his continual exertions and his enthusiasm or "pep" deteriorates as the day advances. To minimize this inevitable fatigue is a step toward higher efficiency, as the conservation of physical energy, often expended in unproductive labors, is very often of primary importance. Apart from the actual handling of the work to and from the machine, the manipulation of the latter usually involves considerable exertion on the part of the workman, which in time affects his ability to perform his task as accustomed to during the earlier hours of the day.

A feature in connection with the operation of machine tools, more especially

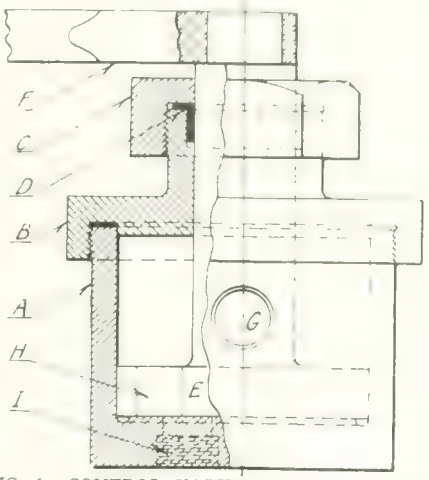

FIG. 1. CONTROL VALVE FOR AIR CHUCK.

lathes of the heavier variety, is the backing off of the carriage after a cut has been accomplished. In the case of quantity production the labor necessary for this return operation requires the expenditure of much energy which might be profitably utilized to better advantage in other directions. This possibility was early recognized by many manufacturers, and with the purpose in view of relieving the workman, and at the same time facilitating the operation of moving the heavy carriage, small long pneumatic cylinders were placed on the back of the lathe for rapidly returning the saddle to the extreme back position (Fig. 3). The cylindrical portion A of these cylinders is made from suitable pieces of smooth bored tubing, the heads B B being held in position by means of the long rods C. The cylinder is supported by the brackets D and E. The outer end of the piston rod F is secured to the ell bracket G that is bolted to the under side of the machine carriage. When the cut is being taken the piston is free to travel in the cylinder, and when the cut has been completed the air is allowed to enter the cylinder at the end D and the piston and likewise the saddle is forced back to a non-working position. Where compressed air is in use for the operation of chucks and other appliances the installation of a quick return labor-saving device on heavy tools will often prove of inestimable value.

### Vertical Chucking for Bench Work

In the manufacture of shells many plants require the use of nose plugs for certain of the machining operations. Previous to the adoption of compressed air for such purposes, the shells were usually placed in an ordinary vise or special clamping chuck and held while the plug was screwed in. The manual requirements in the tightening and relieving of these primary chucking devices were not conducive to maximum output, so that many establishments have replaced these appliances by others operated by compressed air, assuring more rapid and reliable operation. Fig. 3 illustrates a vertical air chuck adapted for the holding of shells while the nose plugs were screwed in. The body A, forming the outer casing of the chuck, is secured to the bench as shown. The steel collet B, made in three sections, has a flange on the inner end that fits in a groove in the piece C. The piston rod is connected to this piece as shown at D, the lower end of the rod being secured to the piston E. The cylinder is suspended from the chuck body

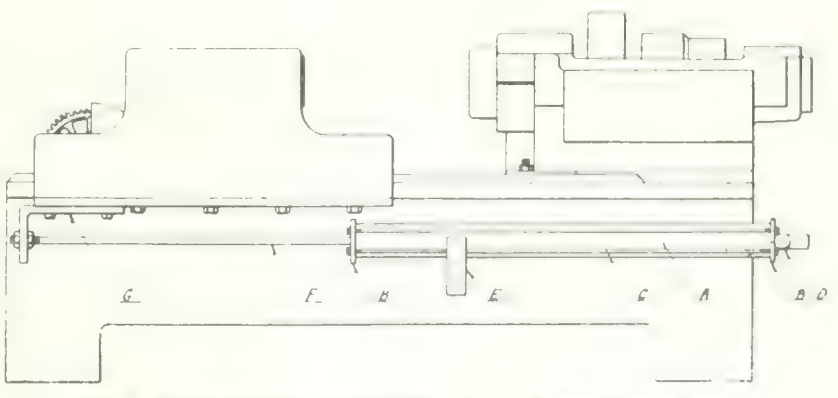

FIG. QUICK RETURN ATTACHMENT FOR LATHE CARRIAGE

by means of the tube F, the gland G being fitted to prevent air leakage. The cylinder is composed of three parts, the cylindrical portion I and the two heads J and J, the upper one being fitted with a stuffing box as shown, the whole being held by the bolts K. Openings are placed in both heads for air supply, L being the pressure side when holding the work and M the entrance for release of the chuck, the control being obtained by a three-way valve.

### Pulling Band Over Shell

When placing the copper band over the shell and locating it in position in line with the groove, preparatory to compressing it in the hydraulic press, considerable difficulty has often been experienced owing to the necessity of forcing or hammering it to the required position. This process not only retarded the output, but very often the band would enter at a slight angle, so that when pressure was applied it was sometimes found that the fit of the band in the groove was not uniform, consequently giving rise to possible rejection when inspected. Often such a band when taken from the press would appear perfectly sound, but after being machined slight defects would occasionally develop which, upon inspection, would necessitate the removal of the band.

Efficient methods, in what might be classed as insignificant details, are very often found to be economic factors in the problem of quantity and quality production. Where some simple and easily constructed device can be readily adapted to eliminate, or even reduce, the possibility of mistake or faulty work, the initial expense should not deter one from

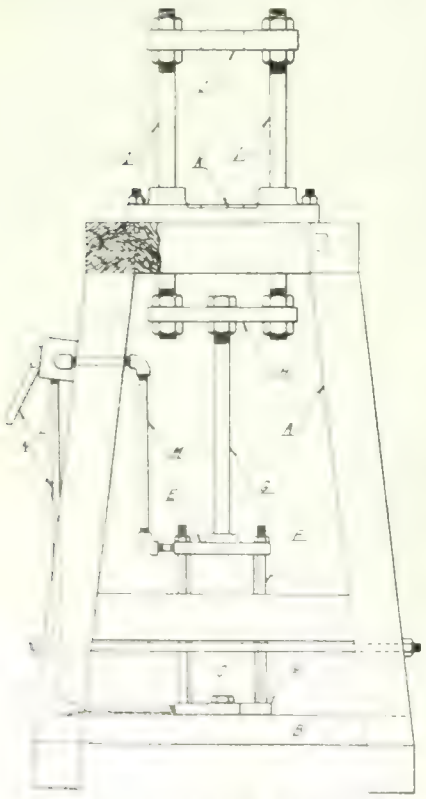

FIG. 4 APPARATUS FOR PULLING BAND

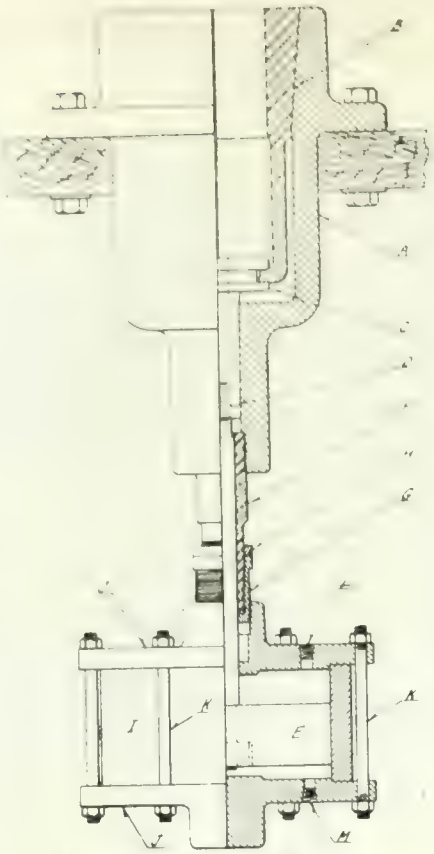

FIG. 3 AIR CHUCK FOR SCREWING IN NOSE PLUG

trying it out, if only to test its serviceability. A little experiment often results in a great saving of time and material.

The sketch of the "press" illustrated in Fig. 4 shows the method adopted in one shell plant for overcoming the trouble arising out of the unevenly pressed bands. With this device the copper bands are drawn over the shells quickly and uniformly, so that it is a rare exception to have a shell rejected on account of a misplaced band. The framework A is made of 3-inch square scantlings, the bottom brace B acting as a support for the pneumatic cylinder C; this cylinder is made of a straight tube and two heads held together by the bolts F. The upper end of the piston rod is connected to a plate H, the outer end of which carries the draw bolts I, the plate J on the top of these bolts being bored in the centre to pass freely over the body of the shell. The base plate or bolster K is provided with a recess of sufficient depth to allow the band to be pulled to a definite position in line with the prepared groove. The operating valve L is located on the side within easy reach of the operator. The valve is of the three-way type, so that air can be supplied to either end of the cylinder as desired.

### Pneumatic Clamping Device

During the past few years increasing attention has been given to the application of compressed air for various clamping purposes. By the use of suitable apparatus air operated clamping devices may be brought to a high state of efficiency. If used direct it is essential that the piston packing be perfectly airtight or trouble will eventually develop. However, the general practice is to provide a system of cams or levers to assure positive action of the clamping points. As stated before, two of the great advantages of pneumatic appliances are the rapidity with which the pressure can be applied and the releasing of the workman from the physical exertion required for hand-clamping arrangements. Where heavy cutting is a factor of the work it is absolutely necessary that the pressure exerted on the clamps be sufficient to prevent any possibility of the work slipping under the action of the cutting tools, and to obtain this by the pull of a wrench on a nut or bolt requires a tremendous strain on a man's arms, which, when continued at short intervals, must sooner or later result in fatigue and consequently loss of productive power.

An interesting and highly effective clamping arrangement for heavy work is illustrated in Fig. 5, it being adapted for use on the special Gorton cutting-off machine. The initial pressure is exerted by means of air or water forced into a cylinder placed to one side of the machine; by a system of levers the final pressure on the work is magnified many times. On the out end of the piston rod is a forked cross head that slides on two

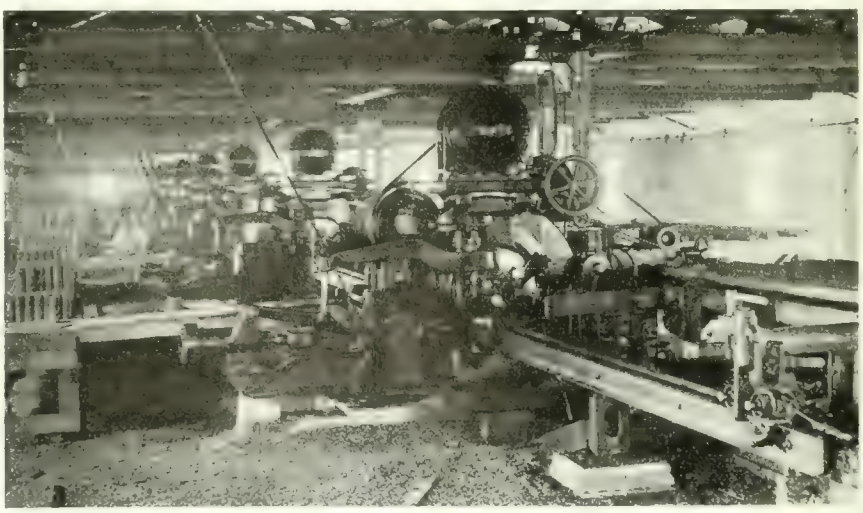

FIG. 5 SINGLE CLAMPING DEVICE ON GORTON CUTTING-OFF MACHINE

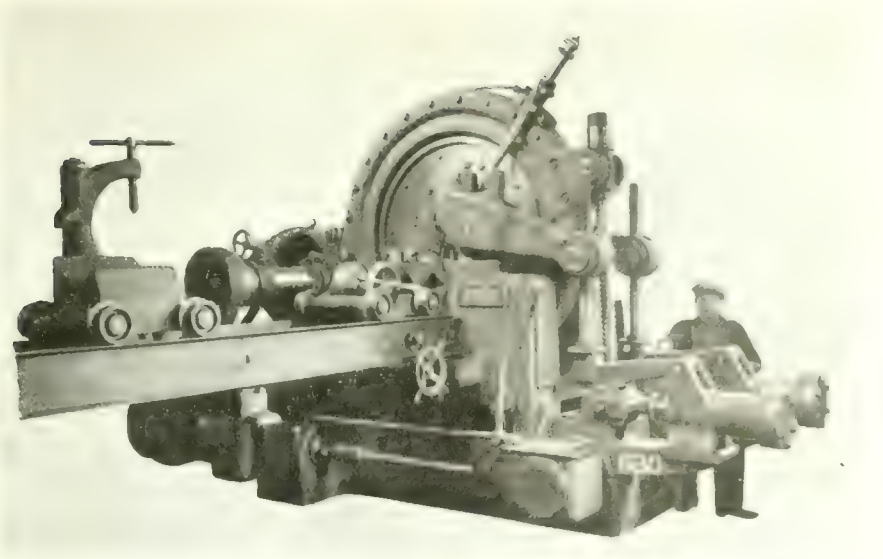

FIG. 6. DOUBLE CLAMPING DEVICE ON GORTON CUTTING OFF MACHINE

steel shoes located horizontally and secured to the top of the cylinder supporting base. In the forked cross head is fitted a steel pin that carries the large ground chilled roll that operates the swinging lever shown. The action of this roller motion is on the principle of the wedge, with the vertical movement becoming less and the pressure greater as the piston advances. The top lever, which is in the ratio of 6 to 1, increases the holding power still further.

Where clamping is necessary on either side of the cutting head the clamps are fitted in duplicate as shown in Fig. 6. The arrangement is similar in each case, but in the double type the fixed rod used between the two levers is replaced by the large adjusting screw to facilitate the operation. This screw passes through a 6-inch cylindrical nut, journaled in the long arm of the main clamping lever. Through the short end of this lever is the main clamping screw, also adjustable, and the lower end is provided with a tempered tool steel dogging point for biting into the work and assisting in preventing slippage of the bars.

### Development of the Self-Contained Spindle

No other detail in connection with machine shop operation has been given greater thought and attention during the past three years than that of chucking. To attain and maintain a high percentage of efficiency in quantity production of any description the handling and holding of the work is of vital importance, not alone from the viewpoint of speed, but also from the viewpoint of service and economy. The abnormal requirements of the munitions making industry have undoubtedly been the primary factor in the development of effective methods for holding shells during machining operations, and the outstanding feature of these chucking appliances is the preponderance of air operated equipment. It is not that the use of air gives a greater gripping power than the hand wheel operated draw rod, but with the pressure exerted being relatively the same the preference is with the pneumatic devices, due to the celerity of its action and likewise to the fact that the workman's energies, which must be severely taxed in the hand chucking process, can be conserved for other and more productive purposes. In the early stages of the struggle for mastery of the shell-making problem manufacturers were forced to adopt many different methods of chucking devices for the various sizes of shells. In the incipient period of munitions activity the equipment then in use was not very well adapted to perform the volume of work that is now possible from the large variety of machines that have been specially developed for certain and specific purposes. However, it was only a short time after the industry was well under way that engineers and mechanical men began to realize the possibilities of the single purpose machine, and in recognizing the advantages of such tools applied themselves to the task of redesigning the existing equipment so that maximum production could be attained.

In reconstructing these machines the chucking of the work was given equal consideration with the machining of the shells, and where a supply of compressed air was available or contemplated the incorporation of air operated chucks or mandrels was widely adopted. With the exception of the variation in the design of pneumatic chucks the principle of their action remains the same, each separate chuck having been developed from the experience or practice of the shop in which it has been used. The impetus that has been given to this particular phase of machine tool construction during recent years has greatly altered the head stock design of those lathes adapted for the special purpose of shell manufacture. To increase the rigidity and make it possible to take deeper cuts and heavier feeds, the chuck proper has been incorporated in the main spindle of the machine so that the body of the shell will be practically in line with the main front bearing, thus eliminating excessive overhang, which often requires an additional steady-rest to support the outer end of the shell or auxiliary chuck.

### Combined Chuck and Spindle

An instance that will demonstrate the evolution of the self-contained chuck and spindle, which, in conjunction with its pneumatic control, materially facilitates the operation of the machines and increases the efficiency of the individual operator, is given herewith. Desiring, if possible, to increase the output of a Hall cutting-off machine, a large railroad shop designed and constructed a special spindle to take the place of the standard one, and fitted it with the necessary collet chuck and air operated cylinder. A sketch of the entire spindle is illustrated in Fig. 7. As can be seen the cast iron spindle A is constructed so as to be as light as possible consistent with ample rigidity and operation. Fitted to the cylinder B, which is threaded to the rear end of the spindle, is the piston C, which in turn is connected to the collet chuck by means of the push rod D, the gland E being provided to prevent the escape of air. In addition to the action of the air the piston leathers are forced to the walls of the cylinder by means of the spring ring G. Supplementing this is a small packed ring H in the middle of the piston width. The head of the piston carries the air connection J. Secured to the forward end of the connecting rod D is the machine steel piece K that carries the tail end of the three uniform sections

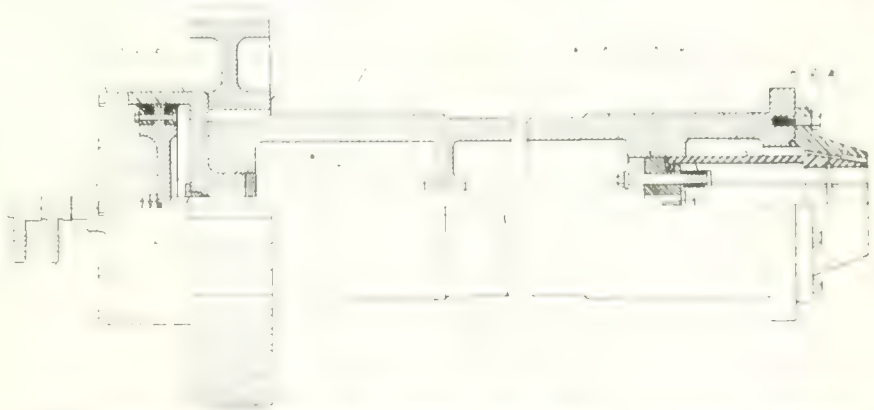

FIG. 7. SPECIAL AIR CHUCK AND SPINDLE FOR HALL CUTTING OFF MACHINE

of the collet jaws. It will be noted that the core of the spindle has a smaller diameter to provide a support for the block K and also the rear end of the jaws. A washer-like plate M is bolted to the front end of the spindle, the interior being bored tapered to suit the angle on the outside of the jaws; these latter being kept in their relative positions by means of three collet keys N. Spring rings O and P are fitted to free the jaws after the air pressure has been removed. When the work is released it is automatically ejected by the bolt Q, acted on by the compression spring R. To provide additional stability to the push rod it is supported midway by the bearing S.

In commenting on this particular chuck the superintendent said that it had been originally equipped with a collet that was solid at the rear, being split for a distance of about seven-eighths of its length from the nose or open end. As the collet was initially bored to a normal diameter it was obvious that a shell under size would have a tendency to receive the maximum pressure at the extreme forward end, while a shell over size would show a tendency to take the grip at the back. In order to eliminate these objections it was decided to make

To emphasize the importance of carefully fitting the piston to the cylinder the following incident may be of interest. Shortly after the change was made on the Hall cutting-off machine, mentioned above, complaints were made that

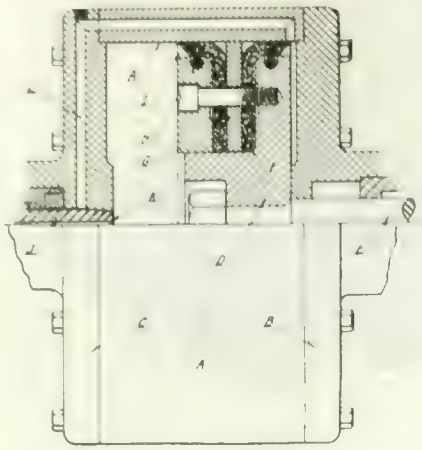

FIG. 8. ARRANGEMENT OF 6½ IN AIR CYLINDER.

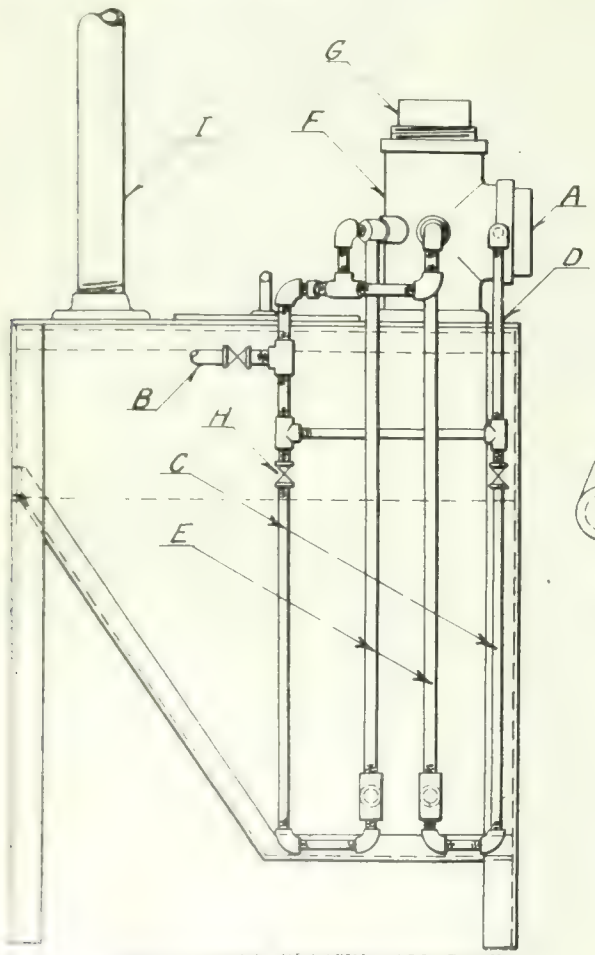
this particular chuck would not hold, the shell showing a tendency to slip when the tools were forced into the metal. Upon examination it was found that the air was leaking past the piston packing, creating an equal pressure on either side, and destroying the initial grip of the jaws. This trouble was soon overcome by smoothing out the bore of the cylinder and using sound packing leathers.

### Special Piston Design

To be assured of positive and reliable action of any air operated appliance it is essential that the initial pressure acting on the piston should be maintained during the desired period. To attain this it is obvious that the bore of the cylinder should be smooth and parallel, and that the leathers or other packing rings should have perfect contact with the cylinder walls. An arrangement of a 6½-inch cylinder that has given very good satisfaction is shown in the sketch Fig. 8. The body A is made of a short piece of casting bored to the required diameter and fitted with two heads (made from the same pattern) held in position by the bolts shown. This method provides a convenient and economical means of repair, as the cylindrical portion, which is most liable to wear, can be readily renewed with little loss of time; a feature of considerable importance when a machine tool is a unit series production.

The piston D is made in several sections with the leathers separated by the middle washer, the whole being firmly held together by the clamp washer and bolt shown. It will be noticed that the leathers are forced to the walls by the expansion of the spring rings H, and in addition to this the leathers are beveled at I to allow the air to exert a side pressure and thus increase the tightness of the joint. In the construction of this cylinder no reliance has been placed on a spring for releasing the chuck, the piston



...ND BLASTING APPARATUS.

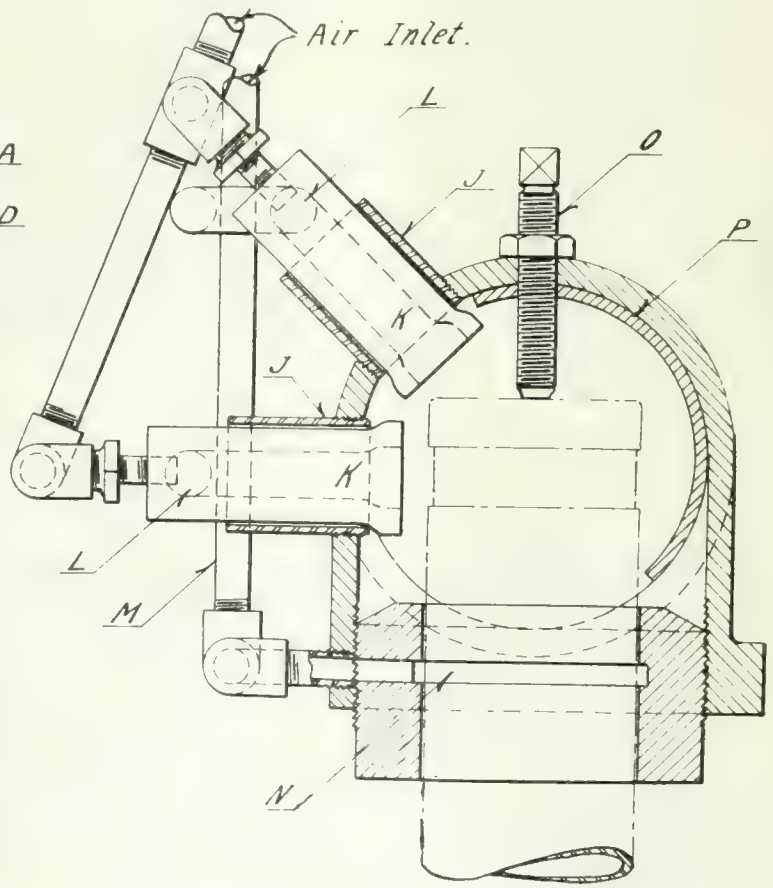


FIG. 11. DETAIL OF BLASTING NOZZLES.

being under positive control by admitting the air to either side of the piston as required. By this means the same cylinder can be used for a pushing or pulling action on the chuck mechanism. To force the piston in a forward direction the air enters the central passage K, and for the return movement the air is admitted into the space between the central tube J and the bore of the head C, and thence to the passage L to the opposite side of the piston.

A somewhat similar piston arrangement is illustrated in Fig. 9; in this design the separating washer is eliminated, but otherwise the construction is much the same. It will be noticed that the duty of the spring rings shown in the previous sketch is performed by the air itself, which is admitted to a chamber back of the piston leather and acts at right angles to the movement of the piston. It will also be seen that the left-hand leather is protected by a ring of metal that forms one side of the air pocket.

### Sand Blasting Apparatus

Sand blasting is a process that has been in use for a long period, but its progress has been greatly stimulated during recent years through its adaptation for the cleaning of shells after the heat treatment or hot-nosing of the open end. Before the copper band can be pressed on it is imperative that the scale created from the heating process be entirely removed from the surface of the metal to avoid serious complications during subsequent operations. Various designs of sand blasting devices have been constructed for these cleaning requirements, both for the interior and exterior of the shells. Many of those now in use have been developed in the respective shops, which has been responsible for the variation of their construction, although the principle of their action is invariably identical—that is, the vortex of the air and sand, as great velocity is required to cut the scale that clings to the metal, leaving the surface smooth and clean.

The general arrangement of one of these shell-making accessories is shown in Fig. 10. The sand supply is contained in a sheet steel tank that forms the body of the apparatus. In order to clean the base and rifling groove of the shell it is placed in the side opening A of the large standard pipe tee F, the top end of which is closed by the plug G, the lower end being fitted to the top of the steel tank. The air supply, at an approximate pressure of 8 lbs. per sq. in., enters at the point B, and through the system of piping forces the sand from the tank to the tee at the top. The air passes through the pipes C C and forms a suction in the sand delivery pipes E E, so that the sand is drawn upwards and blown with considerable force to the desired point on the shell body. An auxiliary supply of clean air is discharged through the pipe D for a purpose explained in the following paragraph.

In Fig. 11 is illustrated a sectional detail sketch of the nozzles and blasting

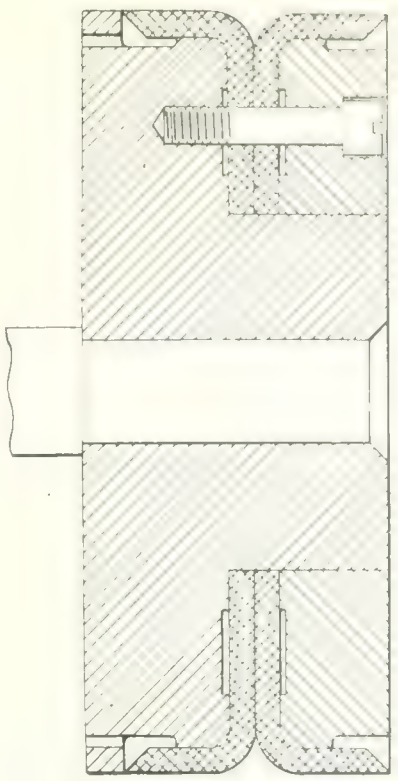

FIG. 9. ALTERNATIVE ARRANGEMENT OF AIR PISTON

chamber. Threaded to the body of the tee F are the two casings J set at an approximate angle of 50 degrees with each other. Through these the discharge nozzles K are located, and the mouth is enlarged to spray the sand and also to provide a check to the flying sand to prevent the same from backing up through the space surrounding the nozzles. As the mixture of air and sand is drawn up through the opening L it receives the additional force imparted by the clear air entering from a horizontal direction. Leading upwards from the cross pipe M a portion of the clear air is delivered through the pipe D (previously mentioned) and into the groove N that is cut in the bore of the bush A. The object of this is to form a film of air about the shell and to assist in preventing the sand from coming out at this point. The position of the base of the shell in the sand blasting chamber can be regulated by the adjusting screw O. To avoid the destruction of the cast iron tee the steel plate is fitted in so that, as the action of the sand affects this plate, the same can be renewed by removing it through the top opening of the tee and inserting a new piece. The air after being used passes out through the 2½-inch exhaust pipe I, the sand, owing to its greater weight, remaining in the supply chamber.

### Feeding of Cutting Tools

An interesting application of compressed air for the operation of a machine tool is shown in Fig. 12. It is here used for the feeding of facing cutters to the end of cast iron fuses. In the manufacture of these cast iron fuses it was found advisable to remove the rough skin before the same were handled in the automatic machines owing to the rapid destruction of the cutting edges of the tools when removing the hard scale. The adoption of the method here described facilitated the operation and greatly increased the efficiency of the finishing machines. The cast iron fuse A is held

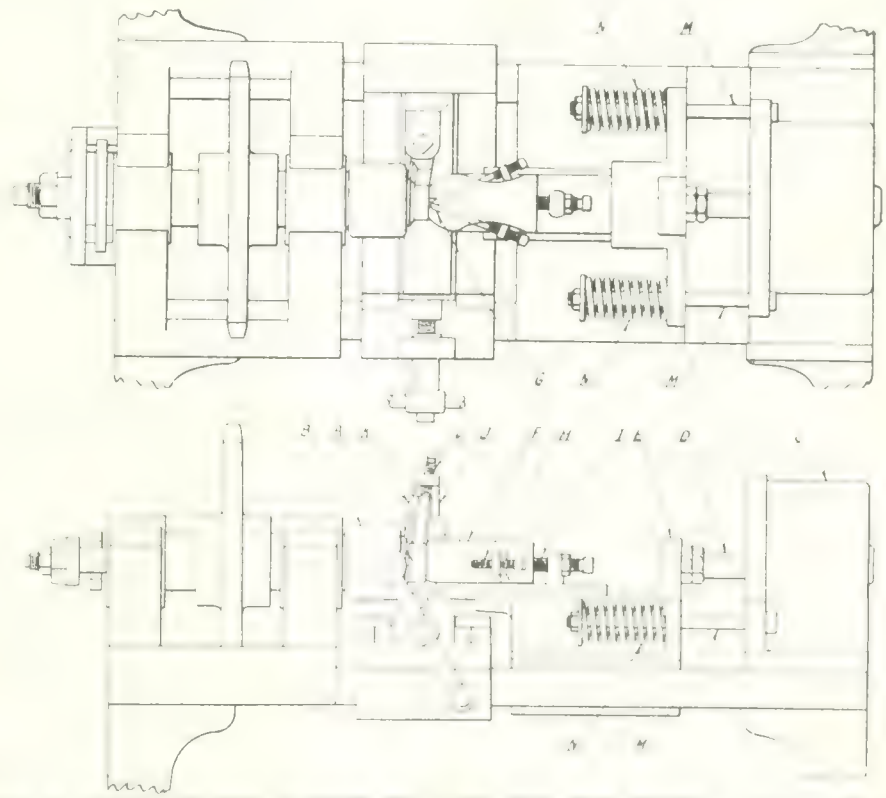

FIG. 12. ROUGH TURNING MACHINE FOR CAST IRON FUSE BODIES. AIR-OPERATED CARRIAGE IS RETURNED BY HELICAL SPRINGS

ing in the chuck is bored taper to fit the driven by means of small raised portions cylinder C is secured to the end of the machine bed, the outer end of the piston being connected to the longitudinal slide centre line of the machine, with the cut- plug contained in the centre for regulating the depth to which the tools shall enter the work. The pressure applied for this facing operation is derived from the air cylinder. At the back of the cross slide is located a bracket that carries another tool K for roughing off the metal on the body of the fuse; this tool is adjustable to height by means of the screw L. While the operation of these tools can be made simultaneously, the general practice is to allow the facing tools to accomplish their work and, while the stop block is pressed against the end of the fuse, the cut on the outer surface is taken, the action then being more rigid and regular. When the fuse has been roughed off the air is released and the tools are backed off by the reaction of the springs N pressing against the washer on the bolt M and the flange of the rod E. One of these springs is placed on either side of the carriage so that the thrust will be uniform.

### Cleaning Powder Chamber

One of the requirements in the manufacture of shrapnel shells is the removal of all foreign matter from the powder chamber after the parts have been assembled. The natural method of accomplishing this is by means of a blast of compressed air forced into the central tube which will, in being exhausted, carry with it any dirt that may have lodged in the tin powder cup at the base of the shell. When these shells are loaded their approximate weight is 18 lbs., and in the handling of large quantities it requires considerable energy to maintain a production consistent with the cost of the operation. In order to facilitate the removal of such heavy particles that might not be removed unless gravity was resorted to, the arrangement shown in Fig. 13 was adopted by one concern for this particular duty. A cast iron bracket A was secured to the side of a bench in almost a vertical position, so that the shell could be placed in with the open end downwards, the nose resting in a suitable hole in the bottom flange B; the upper end was provided

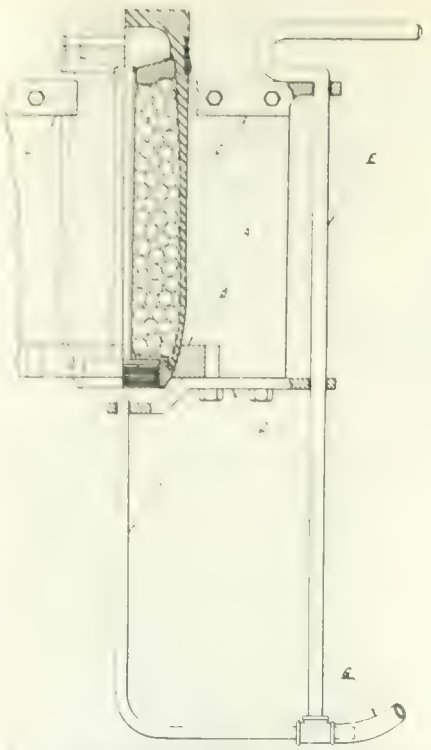

FIG. 13. CLEANING OUT THE POWDER TIN IN SHRAPNEL SHELL.

has been placed in the fixture and the air turned on, the rod E is raised and lowered a few times, which elevates the pipe F into the central tube and all dirt is removed, heavy portions falling by their own weight.

## WOMEN WORKERS IN A FORMERLY EXCLUSIVE FACTORY

By G. C. White.

IN these days of munition industries when such large quantities of men are being employed the manufacturers are somewhat at a loss to know where the help is to come from. The answer is female help. Women have proven that they are as intelligent as men and they certainly are more careful, moreover, being largely employed on specialist operations a great mechanical knowledge is not necessary but rather greater concentration of effort and dexterity.

The great secret of success in using women is to conserve their energy. Not being as strong as men the hours must be shorter, rest rooms should be provided, they should have backs to their chairs and the work should be handy to the machine and should not necessitate lifting or unnecessary handling or carrying. Statistics show that after 8 hours production drops and the gang should be changed. If the work is of such a nature that it can be placed on pegs on trays, in holes on boards or in boxes, a man can look after the handling from machine to machine. Women have and are also being used as tote box carriers.

### Peculiarities of Women

Women must have more definite instructions than a man as to how to use their hands and frequently it is necessary to repeatedly spend time coaching them. Some will forget from day to day, others like men try their own ideas which are not always the best. Men will not always do things the way they are told as they think their own methods are superior, whereas most women will take your suggestion and even though the movements are awkward they will persevere and ultimately increase the output. A man will suit himself when your back is turned.

Toolsetters should be employed to make all the adjustments and where only a drill or similar tool requires changing the operator will do this herself. Men will increase the repair gangs' cost by adjusting and interfering with the details of the fiixture or machine, women will leave those details with which they are unfamiliar severely alone.

Where small fine delicate work is being done a woman's fingers are more suitable than a man's and if a detailed comparison is made they will soon demonstrate their superiority.

Many women are clerks and time and piece work records are among their various occupations. The class of work to which they may be put varies with their character and interest and the better judgment one uses in assigning them to the various classes of work the better will be the ultimate results.

### Their Capabilities

On the Continent where compulsory military service is in force and was before the war the women carried on the business, or ran the farm as the case might be. If women can do this or heavy work similar to what they are doing on munitions in England and France where not so much attention is paid to their comfort, and where there are no such organized carrying systems as we have on this side, why should they not then do our work? Of course our type of woman is entirely different but from my own personal experience I can say that if due thought is given to their strength, mental ability, etc., and if conditions are made to suit each individual, there will be no reason to worry about what a woman can do, as she can and has proved herself to be as efficient as a man but we must not try to make a mechanic of a woman in 10 days and compare her with a man who has been on the job as many years.

## THE LEAD ACCUMULATOR AS A FACTOR IN TRANSPORTATION

By C. T.

IT is a rather surprising fact that the lead accumulator, as a source of motive power for electric pleasure vehicles, trucks, factory trucks, etc., has not become more general, considering the number of good sound business reasons in favor of its use in such applications. A little study of the accumulator itself will enlighten the reader on the main conditions retarding its adoption.

### Early Forms

The "box of power," which Lord Kel-

vin, then Sir William Thompson, was so enthusiastic about, when he received it from Paris, had a great many serious defects. It was the first of the lead accumulators, in which the oxides were pasted on the lead plates, instead of being formed on them by the electric current, in the expensive way that N. Plante had adopted. It was followed a very large number of other forms of pasted plates, all of which were subject to the same faults; the paste was liable to chip off, and the plates themselves tended to bend towards each other, thus short circuiting the cell and running it down. Then numerous forms of grids were adopted, all designed with pockets to contain the oxides, so as to prevent them chipping off. The trouble with these was the fact that the oxides change in volume, or tried to do so, very considerably, in the process of charge and discharge, because of small pieces of the oxides being forced out of the grids and hence short circuit followed sooner or later. The pure lead grids also were subject to the same trouble as the lead plates as they tended to buckle and bend towards each other, thus giving better chances for small chips of the oxide to lodge between them. The oxides which were pushed out of the grids also tended to build up a bridge at the bottom of the containing jars, thus short circuiting the plates, when the bridge was complete.

### Improved Types

Steady continuous work of 30 years has gradually eliminated the major of these troubles; the oxides do not as readily come out of their grids, and when they do they are prevented from short circuiting the cells by perforated separators, and by providing the plates with feet, causing them to stand well above the bottoms of the jars.

But after all trouble is only overcome by continual care, periodical testing, and continual charging. In the process of both charging and discharging the lead accumulator, sulphate of lead is formed. During charge, if the operation is properly carried out, the sulphate is all converted into oxides; but if not, some sulphate remains, interfering with the working of the cell as explained below. In the process of discharging, the formation of sulphate goes on more or less continuously. Sulphate of lead is, to all intents and purposes, an insulator in the position it occupies in the lead accumulator. It also tends to break the circuit, to break the connection between the electrolyte and the lead grid. If some lead sulphate is allowed to remain when charging is complete, it practically screens the portion of the lead plate upon which it is formed, from the action of the current, the resistance of the cell being higher in consequence, and its output less. If the discharge of the cell is allowed to continue indefinitely, a screen of sulphate is gradually built up all over the lead grid, which completely puts the cell out of action.

### Care of Cell

It is standard practice now to not discharge a cell below a pressure of 1.8 volts, and 1.85 volts is better; 2 volts being the initial pressure directly after charging is completed. The lower the pressure to which a cell is allowed to fall, the greater is the difficulty in restoring it to its normal working condition. As long as the discharge has not gone too far, and the pressure has not fallen too low, the cell can be restored by prolonged re-charging, sometimes with an occasional discharge. But the restoration is affected at the cost of the lead grids themselves.

The improvements in the lead accumulator have been very much quickened by the advent of a rival in the form of the alkali accumulator. Salts of nickel, and iron are employed, and the whole thing is constructed in a very much superior manner from mechanical point of view. The plates in the alkali accumulator are of steel plated with nickel; and the active materials are carried in perforated boxes made of the same material, the boxes being held in the steel plates in such a manner that there will be hardly any of the troubles that arose with the early forms of lead accumulator. The alkali accumulator furnishes a much lower pressure than the lead accumulator, 1.2 volts per cell, as against the two volts of the lead accumulator, but it is claimed that a smaller weight of cells is required to perform a given work.

## GAS FIRING AND REGENERATIVE SETTINGS

By T. J.

IN the earlier days of gas firing, as applied to retort settings, there were some rather vague ideas current as to the economy just effected. The saving of fuel consumption and the higher working temperatures attained in the retorts were often too hurriedly attributed to the recovery of waste heat. Waste heat is, of course, recovered, and returned to the setting in the preheated secondary air, but all the advantage does not lie merely with this recovery.

The advantages of gas firing as ordinarily practised are chiefly in three directions:—(1) The application of heat. High temperatures are generated in close proximity to the retort, and not as with direct firing at a considerable distance away, where much of the heat applied is in the form of much cooler and rapidly cooling convection currents of gaseous products. The study of flames may be applied with advantage to the question of gas firing of retorts, which is really a question of the application of flames. (2). The regulation of air. This can be accomplished to a very fine point so as to avoid the drop of available temperature due to the admixture of a large excess of air. (3). Regeneration or recuperation. Much heat is in waste products, i.e., gaseous products of combustion (mixed with air), which have passed the retorts and are on their way to the chimney. Any of the contained heat that can be transferred to the incoming air (usually the secondary air) is so much pure gain.

In Europe regeneration and recuperation of heat are used pretty much as interchangeable terms. In America recuperation is applied to the process by which (as in retort settings) the heat of the waste gases is transmitted through the walls of a flue and is given up to the air in an adjoining flue, while regeneration is there chiefly confined to the recovery of heat from heated chequer work over which the hot waste gases are first passed, and then by a change-over valve the incoming cold air is led over the same chequer work. Regeneration in this sense was tried on gas works, but its use was not long continued, though the same arrangement is successfully used on some coke-ovens, notably the Simon-Carves type.

### Recovering Waste Heat

It is often too rashly assumed that all the heat taken to the combustion chamber by the secondary air of an ordinary retort is this recovered waste heat. It is usefully applied heat, but not necessarily all waste heat. Some of it may be initial heat. In cases where the secondary air travels are placed between the waste gas flues and the furnace, some of the heat in that air will undoubtedly be derived from the furnace. As the air is ceaselessly passing through these flues, and thus tending to cool them, this constitutes a drain upon the heat resources around the flues, and thus will certainly withdraw some of the furnace heat. Whether this procedure may be right or wrong may be open to discussion.

It is all to the good to get the secondary air as hot as possible; but no mistake should be made by considering the heat it withdraws from the neighboring furnace as recovered waste heat. It is abstracted initial heat, and its loss tends either to increase the fuel consumption or to lower the temperature of the producer gas. It may seem unnecessary to labor or even to mention the point, but the heat that can be produced from a given weight of a given coke is fixed and unalterable, whether the coke is burning direct to the carbon dioxide, as in direct firing, or first to the monoxide and then to the dioxide, as in gas firing. Still the idea lurks around in some minds that gas firing actually produces more heat from the fuel.

What gas firing really does is to transfer much of the heat production from the generator to the actual setting some 70 per cent. of it. In the same way the use of water on the fire bars, which when vaporized and passed through the furnace generates some water gas, does not furnish any new source of heat. Whatever heat is given out by its combustion exactly balances the heat abstracted in its formation. All that is gained in a thermal sense is the transference of heat from the lower part of the fire, where a high temperature favors the formation of clinker, to a high zone where it is more useful and less likely to entail harmful secondary effects, such as fusing the ash into clinkers.

## FUEL SITUATION IN WAR TIME

[illegible]

Never in the history of the world has coal been of such vital importance, it is the life-blood of [illegible] world-wide war, and the success of the Allies is very largely dependent upon its increased production and careful conservation.

[illegible] to send the surplus coal produced in Eastern Canada to the New England States and from Western Canada to the Western States, Central Canada and that part west of the Great Lakes and as far as Brandon being supplied with American coal.

The total production of Canadian coal prior to the war was 15,000,000 tons per annum, and in the United States between 500,000,000 and 600,000,000; the latter being the production for 1916.

During the year 1917 Canada will produce nearly 2,000,000 tons less, and the United States approximately 50,000,000 tons more than in 1916. But as the increase in consumption is approximately 100,000,000 tons, there is a shortage of 50,000,000 tons to be made up by elimination of wastage.

Sending Eastern and Western Canadian coal to the United States and American coal to Central and part of Western Canada was with the object of sending coals by the most suitable rail traffic routes and waterways, and providing more even distribution.

If the Eastern Canadian coal was moved west it would be against the current of traffic to Fort William, and if Western Canadian coal was moved to Eastern Canada it would put onto railroads the burden of transporting the longest distance on the American continent.

### What Is Expected of Us

The United States Government has been very considerate towards Canada, and will continue to be so, the intention being to treat Canada on an equality with any state in the Union, but, while doing this, they expect and insist that we do the same as they doing, viz., inaugurate a campaign for the intensive conservation of fuel.

It is not the purpose of this paper to point out in what way our share of the deficiency is to be made up, it being principally a matter of good engineering and true fuel conservation in the boiler-[illegible].

Canadian railways have already reduced their annual passenger train mileage by 10,000,000 miles, and have further decreased the fuel consumption by lengthening out the times of other trains and by eliminating fast freights and instead running trains with full tonnage, and by equipping locomotives with superheaters, and the best known modern means of lessening fuel consumption.

The Canadian Pacific Railway has been [illegible] Railway [illegible] helping the cause by breaking up and using old ties for fuel—this even at considerable expense of labor, train service, etc., gathering and handling.

The United States have also made a start in reducing their passenger service and loading their trains to the tonnage limit, thereby affecting a saving of several million tons of coal per annum.

### Action Advocated

I think that we should go further, and I would submit to the consideration of this club the necessity of the mechanical members getting together and inaugurating an active educational campaign among the firemen, both locomotive and boiler-house men.

To my mind this should not be done by printed instructions but by actual illustration by competent firemen. While it is all very well to write a fireman and tell him what he should do, it is far more educational for a competent instructor to show how it should and could be done.

There is a lot of fuel wasted by automatic stokers not receiving intelligent attention from the fireman. The stoker itself when in proper working order will do all that is required of it, but there are, however, occasions when it will not do what it is supposed to, it is then that a properly instructed fireman will give necessary assistance with a consequent saving in fuel.

The majority of our passenger trains, particularly the sleeping cars, are overheated—it being largely left to the discretion of the colored porter as to what is considered a comfortable temperature, the result is that the temperature is kept up to a point that means comfort for the porter and discomfort for the passengers.

Our houses are being maintained at an unhealthy temperature. Pneumonia takes a little more than one man in eight, and therefore it grasps from tuberculosis the grim honor of killing the most human beings.

Man is a marine animal, seven-eighths water, he needs cool air and moisture around him, overheated dry air makes him susceptible to disease, and in a temperature of over 68 degrees it is difficult for men and women to exist healthfully.

If the people can be taught to live in this temperature, the number of pneumonia victims wil shortly decrease. Fresh, cool, moist air is the foe of pneumonia, and persons who keep their houses cool and breathe pure fresh air have no fear of it.

### Normal Temperatures

Celebrated doctors have decided that 65 degrees is ample for persons in robust health actively engaged, 70 is too much, with 68 we have a fair healthy average.

Many activities which involve large consumption of fuel, and many methods of using this fuel, which are practically legitimate in time of peace, will be found susceptible of changes which involve very slight sacrifices of material interests but afford opportunities for considerable saving of fuel.

We have in the past been an extravagant people in the use of fuel, and as the war continues it will be necessary to get down to bedrock in the matter of fuel economy.

Manufacturers of non-essentials should during these war times voluntarily forego the manufacturing of such articles before being compelled to do so by Government direction.

Wherever possible water power should be utilized. In wooded districts, of which there are several in Canada, wood should be utilized wherever possible. One cord of hard wood is equal to one ton of coal, and one ton of coal is released for use in war work for every cord of wood substituted. It will be found that there is a vast quantity of dead wood in many sections of the country. It will also be found that the supply of wood in many communities is sufficient for domestic purposes in these parts. This wood in many instances is destroyed as waste, and its conservation will not only serve the patriotic purpose of conserving coal needed to win the war, but will also prove a measure of economy to the user.

In certain districts prison labor might be used as a means of cutting and collecting wood, where, of course, the labor of the prisoners could be utilized without interference with free labor.

As a matter of fact the one practical and needful thing to-day is to save coal in order that our transportation lines and munition plants may have sufficient to carry on. It may be patriotic and a certain amount of pleasure may be derived from singing "Keep the Home Fires Burning," but the saving of one ton of coal is of more practical benefit towards assisting the boys in the trenches than the singing of one hundred songs.

## OIL PRODUCTION GETS BOUNTY IN AUSTRALIA

THE COMMONWEALTH Government of Australia has decided to offer a bounty on the production of crude oil in Australia. This decision is of great importance to the state of New South Wales, for the reason that the only oil refining works of any importance are in that state.

Oil bearing shale is found in large quantities at a number of localities in New South Wales and the first effort to distill oil was made in 1865. The shale is suitable for mixing with ordinary coal in the manufacture of gas and in normal times is exported largely to Great Britain, America and other countries, as well as to the neighboring states.

Since the war commenced, high freights and shortage of shipping have killed the busines for the present. The principal companies operating in oil production are the Commonwealth Oil Corporation which has extensive works at Newnes, 80 miles from Sydney, and the British Oil Corporation, at Murrurundi, 300 miles from Sydney.

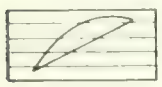
# The Aerial Propeller: Notes on its Design and Construction

By A. Proctor Burwash

*In common with the majority of aeroplane components the aerial propeller has been evolved step by step, the results due to practical experience being applied in successive steps until a degree of perfection is obtained far in advance of that which accompanied initial efforts. As a product of technical deduction and skilled workmanship, the aerial propeller is probably unequalled in its particular realm.*

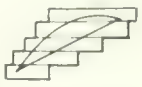
AN aerial propeller is composed of a number of laminations dressed to required thickness and glued together. Both the number and thickness of laminations vary with the size of the propellers and opinion of the designers. Thicknesses from 11/16 to ⅞ are commonly used, while five and six laminations are quite frequent.

In the earlier days of propeller building these laminations were boards of the same width forming a block when glued together, the cross section of which was a parallelogram. From this block the propeller was shaped out. As will be seen from Fig. 1, the finished blade requires only a comparatively small diagonal section of this block, the major portion being wasted. The shaping of the laminations (see Fig. 2) eliminates a portion of this waste and is now in general use.



Laminations Unshaped

FIG. 1



Laminations Cut to pattern

FIG. 2

### Principles of Design

The mechanical principle governing the action of the propeller is the same as that of the wings. The blade of the propeller must be considered as a number of sections attacking the air at different angles of incidence and at different velocities. For each of these sections the relationship of the various forces is the same as in the plane or wing—$Q = K\ S\ V^2\ i$, where:

Q is the pressure in kilogrammes on the plane approximately at right angles.

K is the lifting efficiency (determined experimentally).

S is the area of the plane in square meters.

V is the velocity or speed at which it meets the air in meters per second.

i is the angle of incidence expressed as a decimal fraction expressing the relative slope of one side to the other, in small angles the sine of the angle (see Fig. 3).

While variation in different propellers, either of the true screw or variable pitch type, is governed by actual performance, it will be readily seen from the above formula how great an effect any springing of the blade, due to torsional stress, would have. This tendency is overcome by some designers by having the centres of pressure in the various blade sections in a curved line sweeping slightly away from the leading edge as it proceeds from the hub to the tip. When the centres of gravity are in a similar curve the centrifugal force has a tendency to counteract the strain due to resistance. In still other propellers the centres of gravity of the various sections form a line at a slight angle forward to the axis. In this case the centrifugal force tends to offset the strain from the thrust of the propeller. By combining these arrangements the resistance, torsional and thrust stresses can be fairly well neutralized, tension alone remaining.

The outline of propellers varies greatly, some designers being influenced by the considerations given above and others ignoring one or other of them. Generally speaking, the blade is a narrow ellipse, or semi-ellipse; some with squared ends. The width at the widest point is approximately one-tenth of the diameter. The cross-section (Fig. 4) shows the forward side of stream-line shape, while the rear side is either flat or slightly convex. The thickest point in the cross-section and also the deepest point in the convex side are about one-third of the blade's width from the leading edge.

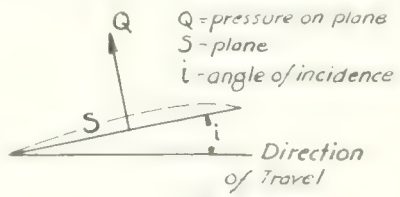


FIG. 3

### Selection of Material

The woods in general use in America to-day are black walnut, mahogany and white oak.

The question of a wood's suitability for successful gluing and its tendency to warp under changing climatic conditions must be considered, together with its strength under the various stresses, hardness, etc.

Only quarter sawn lumber should be used, which makes possible the placing of the grain in right relation to the face of the propeller.

The question of securing seasoned lumber is, and will be, a more difficult one as time goes on. The use of dry kilns has already been resorted to. Great care must be taken to guard against "case hardening" or the setting up of internal strains. The recent development in dry kilns with accurate control of humidity and heat are said to be producing very satisfactory results.

The greatest care has to be taken to eliminate all knots and other defects.

Selected hide glue is used, careful inspection being made by standard methods. A shearing strength test of 2,200 lbs. per square inch and viscosity test (comparing glue tested) with a standard sample of proven efficiency are two of the principal tests recommended in good practice, and should be made at frequent intervals.

The varnish used in the finishing pro-

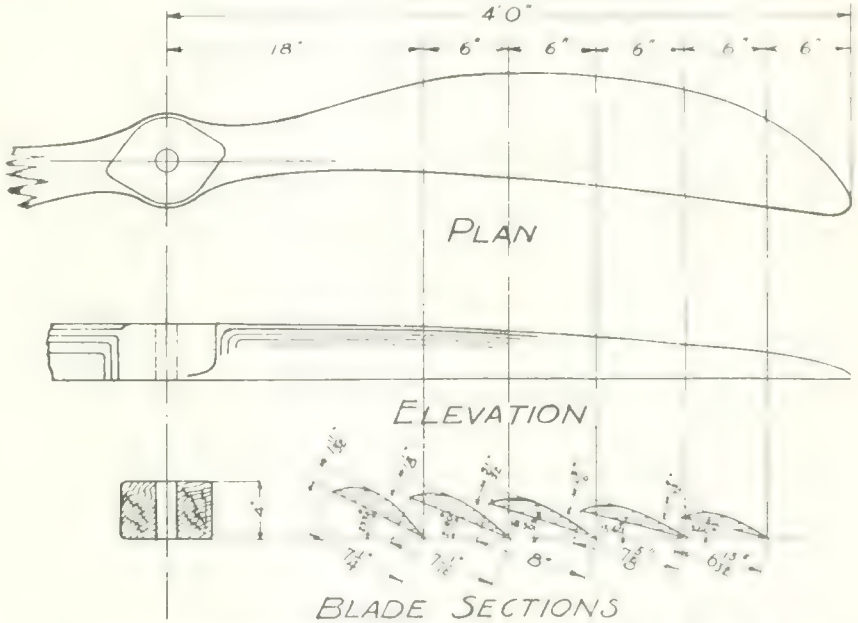

FIG. 4 PROPORTIONS OF TYPICAL PROPELLER AND BLADE

plane."

Machining Operations

boards which have been dressed and kiln

This is followed by the first centre boring, usually 1⅛ in. in diameter, and surfacing down to required thickness, which last operation should be done with great care. The surface is now roughened with a tooth plane to improve gluing conditions. Care should be taken, however, not to impair the dimensions.

the balancing equipment (see Fig. 5). Usually two carefully adjusted parallel rods, about 5 feet from the floor and 18 through the laminations is placed on these bars and the heavy end determined and marked. In the grouping of the laminations composing any one propeller not only should these heavy ends be alternated, but selection should be made to bring the grain at approximately right

The location of the glue room, in addition to convenience in the rotation of operations, should be such as to ensure heating and freedom from draughts. The equipment consists of glue cooker, oven for warming laminations, and clamps or presses. The groups of boards are warmed in the oven, the glue applied, and boards placed in their correct position on a stand with centre pin and clamped, or in the press and the bolts tightened to retain pressure. The gluing and clamping operation should be done in 15 minutes to ensure success. A period of some two weeks should be allowed for the thorough setting of the glue and drying of the block. The clamps are removed after 24 hours, and the rough shaping should also be done during this drying period.

There are already on the market several machines for this rough shaping. Their success is still an open question.

**Bench Work**

A special bench or stand is used with a bolt set in an upright position, as shown in Fig. 6. This bolt passes through the shaft boring in the propeller and clamps it firmly in position.

A surfacing table with a spindle similar to the bolt mentioned above and adjusted with great care, and with the radius marked in suitable stations, is used by the mechanic for testing the accuracy of the blade angles, tracking of the blades and diameter.

An especially adapted protractor and a surface gauge are used in this work (see Fig. 7). The thickness at the various stations and also the correctness of the stream-line side is gauged by a set of templates. A balancing arrangement similar to that mentioned above should also be located here, and the dynamic balance perfected in all positions. There has been a machine built in England which registers the lack of balance in half-ounce inches; this would have many advantages.

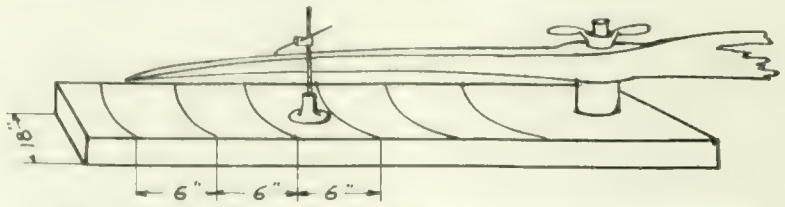

FIG. 6 SURFACE TABLE FOR CHECKING PROPELLER DIMENSIONS

The finishing methods vary in different factories. French finishing is used by some; fillers and varnish by others, also shellac and oil finishes. In all the above methods careful work in the smoothing with sandpaper and steel wool between the coats and in the final polish with pumice stone is required, as the fineness of the polish is an essential of success.

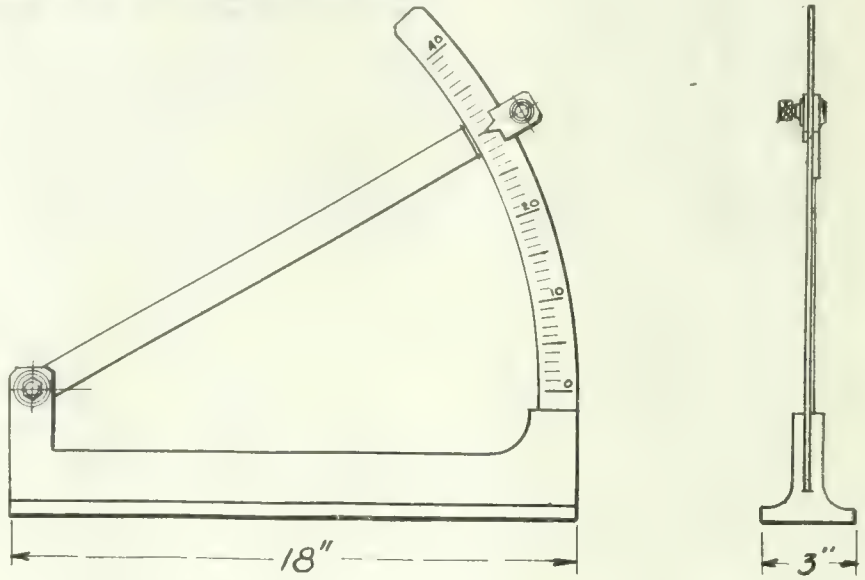

FIG. 7. PROTRACTOR DESIGNED FOR PROPELLER CHECKING

**Inspection**

The inspection should include selection of lumber, testing of glue, and careful examination of failures in glue joints. The checking of the angles, tracking, diameter, width and thickness of blades at various points is done on the surfacing table and the balance is checked, as described above. Any roughness or unevenness in the surface must be eliminated. The balance is watched at all stages of the operation, the final balance being adjusted with additional coats or part coats of shellac or varnish applied where necessary.

DISUSED cotton mills in England are being converted into aeroplane factories and the Cotton Control Board is arranging to supply labor in the various districts where the mills are located.

# Shell Inspection: What a Shell Inspector Should Know-II.

By Chief Examiner

*The prolongation of the war with the increasing importance attached to quantity and quality of ammunition make it more than ever essential that inspection, to fulfill its purpose, must be applied intelligently, however unremittingly. A little knowledge is sometimes dangerous if misapplied, and the author of this article endeavors to make clear the object of inspection, rational methods of carrying it out in practice, and incidentally the disastrous results attending ignorance or carelessness in performing the duties attached thereto.*

THE machining of high explosive shells has been thoroughly dealt with in the technical press and the writer does not propose to more than touch on that subject. It is desired, however, to deal with inspection in detail, and while the remarks apply, to a certain extent, to what is done, or should be done, in the government room, they apply more directly to those engaged in shop inspection.

There are several conditions essential to good inspection—good light; no noxious fumes; good eyesight; no great rush, or excitement; clean benches; also the shells themselves should be clean inside and out. To begin with the inspection of high explosive shell, we will take the preliminary examination first. This of course, varies in the order of operations according to the size of shell, but the main idea is the same. Each dimension has its " High" and "Low" gauge limits. "High" is the term used for the greatest dimension, and "Low" for the least.

### Care of Gauges

There is a way of using a gauge so as not to cause undue wear. Never try to make a gauge fit the shell, but have the shell made to fit the gauge. In other words, don't force the gauges. They are costly things and must be renewed when worn. As they are made to .001"—a thousandth of an inch, and in some cases, such as the screw-gauge to a tenth of a thousandth—it only needs a little carelessness to render them useless. If the shop gauges are carelessly used, you cannot expect to be able to gauge correctly before submission to the government room. Manufacturers always prize a man who takes care of his gauges. Here is another hint. Keep the gauges on a board or in a box when not actually in use; keep them clean; give them a coating of grease once a week; and don't leave them lying about the bench for shells to roll over.

The first operation should be the "visual internal." See that the "bore" is clean, smooth and free from tool cuts, scores and scratches. Look carefully to see that there are no "pits" or "tits" in the bottom. It is very important that the bottom of the bore be free from these defects, because the explosive tends to hug there when the shell is fired. Also see that there are no traces of "piping," "sand holes" or other flaws in the interior. The bottom should be perfectly flat.

As "bores" are a bore and bone of contention in most factories, a shop inspector on the bench should give this question his first attention. It is no use sending faulty ones into the government room only to be sent out again. Rectifications are not only a waste of good time, but are a terrible hindrance to production. Find out what the chief examiner wants, and give it to him. It is just as easy and a good deal easier than taking chances. Don't let the foreman hustle the shells into the government room anyhow just for the sake of saying that so many have passed over your bench in the day. That is often done and is bad policy because it is not production and is the road to nowhere.

### Details of Handling

Now try your "body rings" over each shell. Use them together. The high should drop by its own weight to the full length of the shell and the "low" should rest on the shoulder.

Some firms do not machine the undercut above the container seat, until after "government preliminary," but in any case the threads should be looked at to see that they are of the proper shape, thickness and form, and are not crossed.

Now go over each shell with the wall calipers in three places. In the shop, this is generally done before the preliminary bench but it should be done there as well. Now turn every shell base upwards; try the base recess for depth, flatness and diameter. This is for 18 pdr., 4.5 in. and 6 in. without adapters. In the case of the larger shells adapters are used instead of base plates.

Examine the condition of the thread which receives the adapter. If it is deeper on one side than the other the shell is eccentric. This is a bad fault and will weaken the fit of the adapter. Examine carefully the seating on which the adapter will rest, when screwed home. This must be in good shape, and have no ridges or roughness on the face. The depth of recess in this size of shell and the depth of the flange on the adapter must correspond.

### Visual Examination

After you are satisfied that the base end is OK, lay the shells on their sides and commence the "external visual" examination. See that they are clean. Look carefully on the base and body for flaws—seams, sand holes, hair lines, ghost lines, etc.—and make sure that the tool traverse is not too coarse. A mirror finish is not necessary but a rough shell tends to damage the bore of the gun. Not only that, but the shells, travelling through the air at high speed—2,600 feet per second— would be more liable to "windage" if rough.

The next thing to gauge is the driving band recess, "H" and "L"; after that comes the width of D. B. recess, H and L; then the "form" and "throw" of the waved ribs. These must have a continuous "wave," and, according to the size of shell, must have a certain amount of it shown in the blue-print. If they are not good, the driving band is liable to slip when gripped by the rifling of the gun. This would be very dangerous and would cause the shell to wobble in its flight.

Now try the distance of base from D. B. recess. It is only necessary to put the low gauge over at this stage. Don't forget the base thickness. Base calipers are generally used for this test, or what is termed the pillar gauge. When looking over the body visually, see that the figures of the heat number are stamped plainly and legibly and when stamping the series letter, let it be perfectly distinct. The letter E looks very much like F, and O very like Q. A good government man will not accept a shell with indistinct markings.

### Friendly Advice

The preliminary examination is now over and the shells only require to be washed, if this has not already been done, and they are ready for submission to the government room. Of course, certain chances may be taken by the shop inspector, because although the chief government examiner may not pass certain things, the Assistant Inspector for the District may be able to do so. But the shop should not play upon this fact, as it sometimes looks as if undue advantage was being attempted.

Never, at any time, or under any circumstances, try to put anything over the government examiners. This at once destroys any confidence the chief may have had in the shop inspectors, and always leads to trouble. If the shop inspector is not sure of anything, he should at once enquire at the government room. Then everyone is happy and confidence is created and maintained.

Now comes the fitting of base plates in the smaller shells, and adapters in the larger.

Base plates, when forged, carry the government "acceptance" stamp only, although they are forged in "heats." Adapters carry the code letter, heat number

Base Plate Requirements

.006 in. feeler to enter when the plate is shell. At the same time, it should not be loose when faced. Base plates must be carefully examined for flaws, cracks and sand holes, and should have the corner or sharp edge removed.

A base plate which is screwed in, should have its threads milled properly and should fit corresponding threads in the shell base without any slackness. They have a left hand thread and when screwed home the nipple should be broken off with the force of sending the plate home.

To inspect the adapter, examine the threads for form, depth and general condition. They must be cut away from the face and flange.. The flange must fit the seating in the shell and the corner on the flange must be rounded. Measure the length of thread in the shell and on the adapter. There must be a sufficient number on the one to take all on the other.

### Adapter Hints

When fitting the adapter to the shell, chalk the face of the flange, screw in half way then shake it with the hand to feel the fit. This must be what is termed a snug, mechanical fit. Screw right home. Now put a chisel cut half on the adapter and half on the shell. The adapter must seat to not less than 70 per cent. Now unscrew and note the seating. Then coat the pilot with shellac putty and screw in one thread. Now coat the remaining threads with Pettman cement and screw home till the chisel cuts meet. On a good, tight adapter, the chisel cut will have just passed the chisel cut on the shell. A government inspector always superintends this operation.

Now we come to the "final" inspection of the shell, which varies in operations according to the size and weight of the various "marks" or "patterns." It is interesting to note these. These are the 18 pounder high explosive and the 18 pounder shrapnel; 4.5 in. H.E. marks V, VII and IX; 60 pdr. marks V and VII; 6 in. H.E., marks III, VI, IX and XVI; also 6 in. mark VII; 8 in., H. E., marks III and V; and 9.2 in., H.E., marks II and IX, and after each mark comes the symbol L denoting that the shell is "land service." These are the shells made in Canada at present. There are, of course, many more types, but they do not concern us in this article.

## WEIGHING APPARATUS IN THE FOUNDRY

By C. T.

THE correct and systematic weighing of foundry materials is of the utmost importance if the best results are to be produced with economy and despatch. In the modern foundry the bulk material, both iron and coke, is carefully analysed before purchasing, and also periodically analysed at the factory to ensure that the quality is being maintained. The laboratory apparatus is generally of the best quality, and it is just as important that the various grades of metal should be correctly weighed before being put into the cupola, otherwise the castings will not give the desired analysis.

### Shop Conditions

The conditions which obtain vary considerably in different foundries, depending on the layout of the plant and the nature of the castings to be produced. In most cases it is the practice to have a small stock of material comprising the charges on the cupola platform, although sometimes these stocks are kept on the ground level, the charges being automatically elevated and discharged into the cupola mouth. Probably the most important machine in the whole foundry is that which weighs the various materials comprising the charge. It is, therefore, of the utmost importance that the weighing apparatus at this point should be the best of its kind and the most suitable for the work. The type of machine used is generally of the dormant pattern, of heavy construction, the platform being of sufficient size to accommodate the wheelbarrows or bogies, and the indicating arm of the no-loose-weight type. To enable continuous records to be kept a tape or ticket-recording device may be fitted.

### Special Type

A special machine has been produced for weighing and recording charges which has been widely adopted for blast furnace work. It is not so generally used in ordinary foundry practice, although it is eminently suitable for the work. The apparatus consists of a series of say, six steelyards, three or four steelyards being used for the various grades of pig, one for scrap, one for coke and sometimes one for lime. The steelyards are totally enclosed in a lock-up, the various weights not necessarily being known by the barrowman. The charge hand or other administrative person sets the poises to the various weights of each grade, etc., required. A small trigger outside the case enables the operator to put into use the steelyard corresponding to the nature of the material which is on the weighing platform. The triggers are either numbered or otherwise suitably inscribed to denote the material, the correct weight of which has been set by the poise on the steelyard.

Individual or cumulative weights may be put on the platform—that is to say, the total constituents comprising the charge may be weighed collectively or individually; of course, each constituent must be on the platform separately. To increase the speed of operation and ensure accuracy a pointer, which has a plus and minus range, is sometimes fitted. This enables the operator to see when the correct load is being approached. Also a recording device may be fitted which records the exact weight of each charge, whether correct or in excess or deficiency. This machine is a distinct advance in the weighing of furnace charges, and if properly used and maintained helps to insure reliable castings.

It is not generally desired to weigh the molten metal in the ladles, but machines have been supplied of the suspended pattern, having clock-face dial indicating automatically the weight of the metal as it is poured into the ladle. On these machines special guards have to be fitted to protect the mechanism from the heat of the metal.

### Weighing Finished Product

The weighing of the finished castings may be done on either a truck weighbridge or portable or dormant platform machine, the type of machine used depending entirely on the class of work turned out; the truck machine being used for heavier castings, the dormant machine for castings of medium weight, and the portable machine for light castings. These machines should be fitted with no-loose-weight steelyard, or preferably with tape or ticket recording system steelyards, so that accurate record may be kept of output. A platform or dormant machine should also be provided for weighing the gates, spills and bad castings. This should be placed near the cupola.

The sand is generally weighed in bulk, but it is sometimes desired to apportion the day's requirements. In this case a dormant machine fitted with rails to suit the bogies may be installed.

All the weighing apparatus in use in foundries should be of the heavy type; the bearings, knife edges, etc., protected as far as possible from sand and dirt and dust. The weighing apparatus which is often used in foundries is generally unsatisfactory, the type of machine being unsuitable for the work. They are generally kept in a dirty condition, the parts being clogged with sand particles, so that the resultant weighings are inaccurate, the management thereby not being able to obtain a reliable output and melt loss figures.

Before installing any kind of weighing apparatus in the foundry individual manufacturers should be consulted, for they will bring their expert knowledge to bear on the subject and supply the most suitable apparatus for the purpose. The weighing machines in the foundry, especially, should be maintained in condition by the manufacturer, who usually sends his own skilled men frequently to the machines, this avoiding disputes and unsatisfactory foundry cost figures.

THERE are, at the present time, 32 Heroult electric furnaces in Canada and 22 of other types—in all 54 furnaces using the electric process. These furnaces have a capacity of 173,000 tons of iron and steel, 50,000 tons of ferrosilicon and 8,000 tons of other ferroalloys per annum. The British Forgings plant at Toronto has 10 electric furnaces of the Heroult type and a total capacity of about 72,000 tons per annum, making it the largest electric process steel plant in the world.

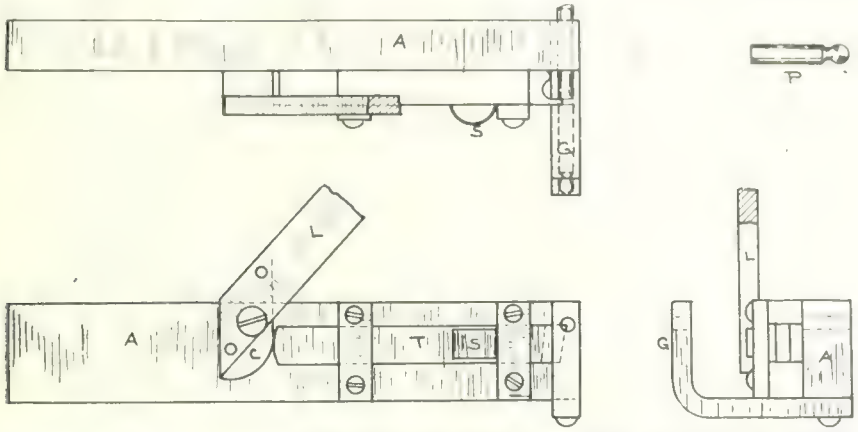
# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

## PIN FORMING TOOL

A. L. Loy

IN the assembly of a machine a number of pins were used such as shown at P. These were driven into casting and used for holding certain springs, the end of the spring being looped over the head of the pin. The assemblers had been in the habit of making their own pins either holding the pieces in a drill chuck or universal chuck on the lathe and then filing for the head and sawing off. The material was ¼ in. cold drawn. One of the assemblers was of a somewhat inventive turn of mind and during his odd time built the tool shown and after that had to supply all the others with pins.



DEVICE FOR FORMING AND CUTTING OFF PINS. ADAPTED FOR USE IN ORDINARY TOOL REST OF ENGINE LATHE

The body A was arranged to be held in the tool post of the lathe and the tool T slid between guides, the end being formed to the proper shape for cutting off and rounding the head of the pins. A flat spring S held the tool back against the cam C which was riveted to the handle. The piece G was used as a gauge and also as a guide when cutting off. The pins were just long enough to extend through the piece C. Needless to say, the shop was not supplied with a screw machine, but in all probability the time was even less when using this tool than it would have been had they been produced in the regular way. A long length was run out of the chuck and started into the tool and as the pins were cut off the carriage was moved up each time.

## ERRORS IN INTERCHANGEABLE PARTS

INTERCHANGEABILITY of manufactured articles is secured by making all details to within known limits of size, and these limits are set with sufficient closeness to ensure a satisfactory fit permissible size of the part to which it fits.

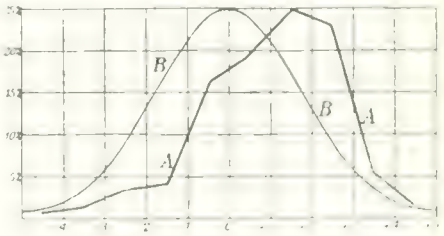
In considering the results obtained by working to limits in the machine-shop, one is apt to assume that the average size of accepted work will be half-way between the allowable limits, and further, that the distribution, between those limits, of the errors in the dimensions will be in accordance with the "law of normal error." These assumptions are natural, and it is usual, therefore, to set even should the largest permissible size of one part coincide with the smallest the permissible limits of size equally above and below the nominal size of the article. Since, however, all machining operations are effected by the removal of metal which there is no means of replacing, it appeared likely that the natural caution of the operator might have a tendency to cause the work to be generally finished a little on the "high side" so as to be further from the danger of being under size.

The point is interesting, because if such a tendency existed, the limits might be set so as to cause the bulk of the work to conform as nearly as possible with the nominal size, and thus to ensure a better general average of fit with the same overall limits of machining.

In order to determine this point investigations were recently carried out in an English factory and the results published in "Engineering" from which the accompanying chart is reproduced.

A supply of 74 finished crank-pins were taken from stock, and their diameters were measured by means of a Prestwich fluid gauge. The instrument was set so that the first pin tested caused the gauge to read zero on the scale, and check measurements were taken several times with the same pin, in order to see that no error due to temperature or other cause was affecting the readings during the course of the experiment. The gauge was graduated in ten-thousandths of an inch, but it could be read by eye to the nearest forty-thousandth of an inch, and the readings were actually recorded to this accuracy. Possible slight errors of parallax, and in estimating the quarters of a division, of course render these readings doubtful, so far as the final figure is concerned, and in collating the data, the readings were grouped into batches, each with a range of one ten-thousandth of an inch.

After all the pins had been measured, they were shuffled and a second set of measurements taken. These were found to agree remarkably well with the first set, especially considering the extreme fineness of the readings. The curve A in the accompanying diagram shows the mean of the two sets of readings, the ordinate representing the percentage of the pins whose dimensions fell within the limits shown on the base of the diagram. Curve B is the curve corresponding to the "law of normal error" and is given for comparison. It will be seen that all the pins came within a range of + or — 0.0005 in., of the nominal size, which is represented by zero on the diagram. The "mode" or most fashionable size was from one to two ten-thousandths of an inch above the nominal size, and 25



CURVES ILLUSTRATING THE LAW OF NORMAL ERROR IN INTERCHANGEABLE PARTS.

per cent. of the pins fell within this range. The "median" or the size above and below which an equal number of pins were found is about one ten-thousandth of an inch above the nominal size. The experiment appears to show that in order to obtain the greatest number of pins of the nominal size, with the same accuracy of workmanship and the same range of limits it would be better to fix the latter at + 0.00035 in. and — 0.00065 in. instead of setting the + or — 0.005 in. above and below the nominal size.

## SETTING MACHINE TOOLS

By D. S. Mann.

WHERE machine tools are placed on concrete floors, as they are in the greater number of cases, it is quite a job to put in the foundation bolts for holding same. Of course, for the larger and more weighty machine no fastening is necessary, and especially so if motor-driven.

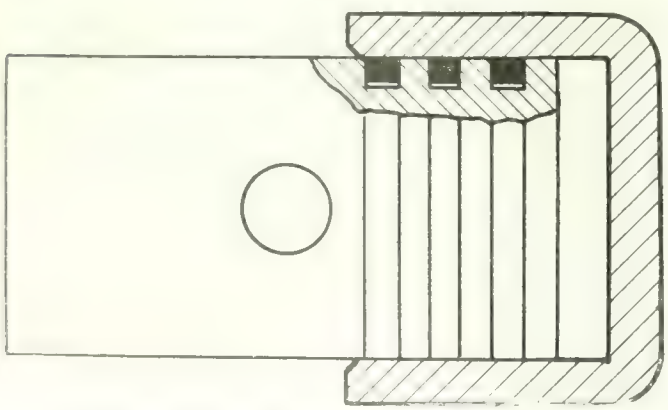
However, the average machine tool will finally work its way out of position either from the belt pull or by being struck with trucks or heavy castings. Several years ago the writer installed [illegible] in a manufacturing shop and, not being quite certain as to their ultimate positions, adopted the following [illegible] were levelled up by means of iron wedges and raised about three-quarters of an inch off the floor. A [illegible] mixture of sand and cement was mixed up with a generous supply of fine iron chips. This was worked well under the edge of the machine so as to have a good wide bearing and was extended out about one inch, giving a bevelled edge entirely around the machine. When this hardened it seemed impossible for the machine to move and, to the writer's recollection, none ever did move. Adding the iron chips formed a very hard cement, and even where castings were rolled against this edge it seemed almost impossible to crack it. If it were desired to move the machine it could, of course, be very easily raised and the cement band then broken up.

## SECURING GAS-TIGHT PISTON RINGS

By A. L. Loy.

TROUBLE is often experienced with the leakage of compression past the piston rings in gasoline engines. This is more often true with the cheaper makes of farm engines, on many of which the standard of workmanship is low. This leakage of compression quite naturally cuts down the power which the engine will develop as well as resulting in an increased fuel consumption. Needless to say it is extremely annoying at all times.

When the piston is being pushed back into the cylinder on the compression stroke the friction between the rings and the cylinder will naturally retard their movement, and they will rest against the side of the groove toward the shaft, leaving a slight clearance on the opposite



ILLUSTRATING METHOD OF SECURING GAS-TIGHT PISTON RINGS.

Now, if the side of the groove and ring as well is rough or uneven the metals will not come in contact completely around, allowing a small space through which the gases will pass. In manufacturing care is always taken to see that one side of the ring is well finished and the same is true in the piston. If these two surfaces are in contact a fairly tight joint may be obtained.

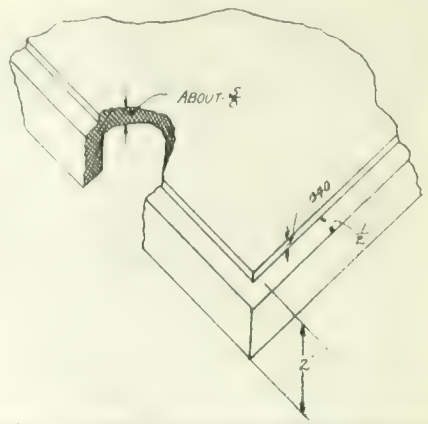
The method here described was seen by the writer in a small gas engine shop which had had trouble in securing perfect results along these lines, and it is well adapted for use in the repair shop also. A casting is bored out to just slip over the rings and piston, bevelled at the edge so the rings will enter easily. A thin mixture of emery flour and oil is poured into the ring grooves and the casting slipped over, and, as it is pushed forward, it will carry all the rings in the same direction so they will rest against the sides of the grooves, when they may be ground to a seat the same as a valve, using a rotational movement. This method has worked out admirably, and has resulted in cutting down the rejections due to leaky rings and pistons.

## PLANING SURFACE PLATES

By D. A. Hampson.

EVERYONE who has gone through a printing office has noticed what are seemingly marble-topped tables with heavy wooden legs standing in the centre of open spaces, with workmen making up "forms" on them. These men are called "stone men," from the material of which these tops are composed, for they are really slabs of marble, which have been used for this purpose almost from the beginning of the art. It is even whispered in some offices that if these stones were turned over the words, "In Memory Of" would be found on the reverse side. The hammering that these stones receive and the laying down of tools results in an abrasive action that wears the surface, so they have to be refaced if used on the best work; then the corners chip off, and it is not to be wondered at that cast iron is taking the place of marble and the iron imposing surface has become the standard modern equipment.

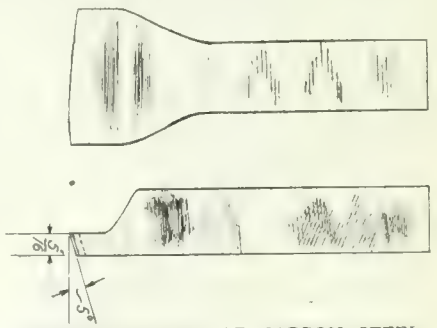
These imposing surfaces are nothing more than large surface plates, but much lighter than a standard shop surface plate of the same size. Take for an example a surface 40 in. x 60 in., which is a good average size; a good surface plate would weight at least a ton if as large as this, but the printer's surface weighs only 500 lbs. in the rough, with most of this in the top itself, the ribs being widely spaced and not over 1¼ in. deep. The finished casting must present a smooth surface, perfectly true, and for shop reasons, if for no other, the thickness should micrometer the same at all four corners and this thickness for printers' reasons must not be over 2 in. Solid blocks about 4 in. square are cast in the four corners for the legs to rest on or fasten to, and small pads are formed at the intersection of some of the centre ribs for additional facing spots on the under side.



PART OF CAST IRON IMPOSING SURFACE

As the castings come in from the foundry they are put on the planer, with the top or final working side uppermost, and after an approximate levelling up are roughed off. The wider ones are roughed with a tool in each of the two cross rail heads. Then a flat tool is substituted for the roughing tool and the surface gone over with a wide feed to even up the two cuts and give a general bearing when turned over. The cutting on the bottom does not have to be particularly smooth, but must be accurately done, therefore the casting is carefully papered up and clamped.

Then when the casting is again placed right side up the unevenness which was the excuse for papering before is taken off with a flat tool. The clamps are loosened, and if there is any spring over any of the clamping points or bearing surfaces, a cigarette paper or two will fix it up. The finishing tool, which is a sort of semi-spring tool, is run over the top. This cut should be a very light one; often the casting does not clean up with just one cut and another must be taken. To test the accuracy of the surface the clamps are taken off and the casting laid



FINISHING TOOL OF CARBON STEEL

on a clean portion of the planer table. Then a standard straight-edge is tried at right angles and diagonally, and must hold two cigarette papers at any point in any direction.

Some will ask why a spring tool of the

gooseneck type is not used. The answer is that the tool shown is better. It is not so springy as the gooseneck, hence it is quicker, and its cutting edge is sufficiently far back to overcome any pulling-in from the bending of the tool itself. So far as the distance that a tool sets ahead of the planer uprights is concerned that argument is purely theoretical when finishing cuts are being considered. The normal working fit of the slides is present, whether the tool cuts a foot ahead or a foot behind the uprights. Printers' machinery has many thin, light castings that must be true, and the tool under discussion has been found to give most satisfactory results. As compared with the gooseneck tool, the cost of forging is but a fraction. Finishing feeds from ¾ in. to 1¼ in. are used. The tool is set by trying cigarette papers under the sides. A broad oilstone is used to produce a cutting edge smoother and truer than the grinder leaves it.

For printers' uses a flat called a rabbet is cut all around the edge of the iron imposing surfaces. This is 0.040 in. deep by about ½ in. wide. The cuts on the long sides are made after the last finishing cut before the casting is taken off. The shops that have an open side planer turn the surfaces for the end cuts. Those that do not generally use an extension and turn the castings, making a setting for each end. Again, there may be a wide planer in the shop, but as the surfaces run up to seven and eight feet in length, these wide planers are few and far between. In the writer's shop this work is done in an altogether way—an old-fashioned way—by hand. The same tool used on the sides is turned and the hand cross feed used to carry the tool across and back. With a crank at each end of the screw and a husky laborer to help, it is a short job—in fact, is done quicker than any other way. The cut on the two ends of a 40-in. surface is done in a half hour. No extra settings are required.

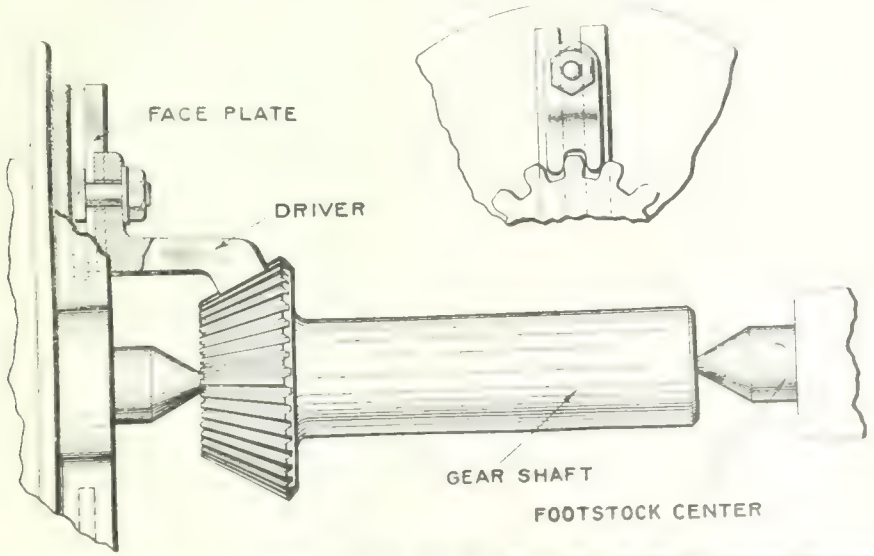
## SIMPLE METHOD OF DRIVING BEVEL GEAR SHAFT

By Howard W. [illegible]

THE accompanying illustration shows a simple driving arrangement for a bevel gear or spur gear shaft, so that when the shaft is put on to the centers of the machine the little driver automatically engages the teeth in the gear and furnishes the means for revolving the shaft while grinding. The illustration pictures a bevel gear in place, but it is equally effective on a spur gear, if the engaging end is made of the right form and shape to fit the spur gear.

As the center wears back it is evident that the driver can be moved in the slot of the face plate to allow for the proper adjustment and play for engaging the tooth of the gear. The driver itself is made from a strip of rectangular steel and fits in the slot of the face plate of the machine having a notch in the end which straddles one of the teeth in the gear. The end engaging the gear should be hardened and tempered.

Such an arrangement offers a simple, inexpensive driver and one which is very effective and convenient for taking the work in and out of the machine.—Grits and Grinds.



SIMPLE DRIVING ARRANGEMENT FOR BEVEL GEAR SHAFT WHILE BEING GROUND

## THE EKENBERG PEAT PROCESS

EXPERIMENTS on the treatment of peat by a modified Ekenberg process are being conducted at Chateauneuf, in the Departement Ille-et-Vilaine, Bretagne, France. According to a paper, published in the "Comptes Rendux" of September 3, and Octover 1 (errata), 1917, by C. Galaine, C. Lenorm and C. Houlbert, the peat is first compressed in presses of the Mabille or Aurep types to reduce the water in the peat from about 90 per cent. to 60 per cent.; the peat is then treated with superheated steam at 160 deg. C. for 25 minutes, and then either compressed again or at once dried, which is best done in special chambers, though air-drying may be applied. The product, which is called tourbon, still contains from 20 per cent. to 25 per cent. of moisture, but does not absorb moisture, as it would do if the cellulose in the peat had not been destroyed by the steam heat. The calorific value is stated to be raised by 10 per cent. over that of dried peat: the tourbon yields 61 per cent. of volatile matter, 36 per cent. of fixed carbon, and 3 per cent. of ashes. With suitable arrangement of the batteries of autoclaves and utilisation of exhaust steam, a heat efficiency of from 85 per cent. to 91 per cent. is claimed to be realised in this process, which can be worked throughout the year. The tourbon is fired directly, or sent to the gas works (with ammonia recovery), or converted into power gas for internal-combustion engines; the last-mentioned utilisation has so far proved most satisfactory elsewhere, we believe.

## AMERICAN FOUNDRYMEN'S ASSOCIATION ACTIVITIES

THE War Service Committee of the American Foundrymen's Association has appointed C. E. Hoyt, of Chicago, secretary, and has established offices in the National Union Building, 918 First St., N.W., Washington. From these headquarters will be directed all of the committee's activities in connection with co-operation with the government. Sub-committees on malleable and gray iron castings already have been named and a sub-committee on non-ferrous castings is being selected. A questionnaire has been prepared and will be mailed out to all of the foundrymen of the United States, and from the data thus obtained, a survey of the foundry trade of that country will be made. Information is being sought on the melting equipment, capacity, fuel capacity, etc., of all castings plants, and when compiled this information will be available to all of the purchasing agents of the different government buying departments.

R. A. Bull, Duquesne Steel Foundry Co., Pittsburg, chairman of the American Foundrymen's War Service Committee and a Major in the Officer's Reserve Corps, has resigned, having been called for active duty. He has been succeeded by H. D. Miles, vice-chairman Buffalo Foundry & Machine Co., Buffalo.

The malleable and gray iron sub-committees already appointed are constituted as follows:

**Malleable Iron.**

[illegible]

H. F. Pope, National Malleable Castings Co., Cleveland.

F. L. Sivyer, Northwestern Malleable Iron Co., Milwaukee.

### ORDERLY METHODS

By R. Hamilton

THIS is one [illegible] this is primarily intended for human associations, it is nevertheless equally applicable to the workman in the factory and the immediate environment in which he finds himself, and for which he is more or less responsible. Orderly kept work benches and machines are seldom the "ear-marks" of an inefficient mechanic. While neatness and cleanliness are not always associated with expert workmanship, it will invariably be found that a man's immediate surroundings reflect the skill and efficiency with which his duties are performed. If a man is directly accountable for the condition of his machine or bench, the general appearance of such is a fair indication of his all-round ability. Particularly is this true in respect to that period when a workman is preparing for a new job. Many men pay little heed to the cleaning of their machines or benches between the finish of one job and the starting of another. Under some circumstances this is not always possible or advisable, but in no instance should complete indifference be allowed to prevail in connection with this feature of shop environment. Not only should men as individuals educate themselves to the uplifting influences of better shop conditions, but an energetic superintendent or department foreman should insist upon a strict rule respecting orderly methods.

### PLACING THE RESPONSIBILITY

By R. M. Q.

THE factor of spoiled work and its relation to machine shop efficiency is a question of considerable importance in the operation and maintenance of the average factory. Referring particularly to that class of work requiring a certain degree of skill for its achievement, it is often true that the article, both in its preparation and production, must pass through a number of hands before it is finally completed. To eliminate the possibility of error or mistake during the process of manufacture is one of the essential factors of efficiency, and if it were not for the variable qualities of the human element, necessary for accomplishment, the attainment of the purpose would be entirely satisfactory. However, no automaton has yet been discovered with infallible characteristics, and, recognizing this, the executives of a factory, who are themselves subject to the [illegible] though perhaps in a lesser degree—must exercise every precaution to avoid the possibility of error while the work is in [illegible] with the same definite meaning as the one who imparts it is a necessary acquirement for effective work. A failing that is only too prevalent in connection with the administration policy of many shops is the hasty manner in which instructions are issued by the foreman to the workmen, particularly when such orders are of a verbal character. In many instances the foreman, before passing out a job to a mechanic, has thoroughly studied the details of production, so that when he is giving the job to the man who is to do the actual work the instructions are based on the study that he has previously given to the question. Unless the workman is of the same way of thinking (mechanically) as the foreman, or that the instructions have been very fully explained, the probability is that the work will be performed in a different way than that intended.

Should cause for argument arise, or through a misunderstanding or misinterpretation of the initial order, the work be inaccurately done, who must shoulder the blame for the spoiled or defective work? Having nothing to verify the verbal instructions previously given, there arises the doubt as to which should accept the responsibility for any errors that have been made. Whenever possible written instructions and, if necessary, sketches or drawings should accompany any orders for work, particularly if the same requires a fair degree of accuracy, and would entail loss of time and material if the work is not properly performed.

#### An Instance

The writer recollects an instance where a toolmaker was given a certain die to make, the foreman giving him a sample of the piece to be made and a brief description of the manner in which the tools were to be designed. As the job was desired in a hurry, it was thought best to have some of the preliminary work started so as to avoid any great loss of time. The instructions were not definite and the workman was allowed to use his own judgment as to the design of the tools. He, therefore, studied the sample and decided on a particular method of die construction, receiving the hurried approval of the foreman. To facilitate the machining of the various pieces they were cut from the bars for shaping and turning. After considerable time had been put in machining the different pieces the foreman—who had subsequently been consulting with the superintendent regarding this particular job—came to the mechanic and advised him that a change would be made in the tool design to conform to certain alterations suggested in the sample. When told that everything had been cut off and partly machined for the piece as it was first intended the foreman was considerably annoyed, saying that too much headway should not have been made until the problem had been more fully discussed. The change necessitated the discarding of considerable tool steel, part of which had been machined.

Such instances as these go to show that in the constructing of dies or fixtures or other tools of accuracy haste is a factor that should be avoided, and in all cases is it advisable to study the problem in hand while preparing drawings and written instructions to which a workman can refer, or leave it entirely to the toolmaker to suggest the design of construction.

### SELLING AND BURNING FUEL

By J. H. R.

FEW problems at the present time are more pressing or more difficult of solution than that of the economic utilization of fuel for industrial and domestic purposes. That the question is of vital significance has been amply demonstrated during the past few weeks by the drastic measures taken by the government fuel controllers, for the utmost conservation of coal in every line of manufacture. In an effort to comply with current regulations and assist in relieving a situation that was rapidly developing into the famine stage, users of fuel were both anxious and willing to co-operate to the fullest extent for a reasonable solution. The essential need of maintaining production was however a feature that invariably prevented a plant from curtailing on the consumption of fuel, for operating the equipment at maximum capacity.

An interesting experience in connection with coal conservation was related to the writer a short time ago, where an institution with a large power plant was induced by the o+cial salesman of a gas concern to use coke forfiring the boilers. The engineer of the plant was not consulted regarding the new developments, as the agreement to "give the coke a trial" was made in the office. The salesman for the gas company interviewed the manager respecting the adoption of coke for the aforementioned purpose. Owing to the poor quality of the coal they had been getting and the convincing persuation of the salesman, respecting the high efficiency of coke as a heat producing medium, the manager finally decided to give the coke a trial, and placed an order for several tons for immediate delivery.

When the engineer was advised that a quantity of coke would be delivered the following day, the jig was up. The manager was informed right off the bat that it was utterly impossible to burn coke on the particular style of mechanical

grate travelling in the boilers. Nothing would do however but that the engineer should make ready to receive and store the supply of coming coke. He nevertheless refused to have anything to do with the "test" and suggested that the gas people supply the fireman for the demonstration, as he would be very willing to learn anything new regarding the firing of a boiler on any class of fuel. So it happened that the next day saw a number of carts discharge their load into the waiting bunkers, and with the arrival of the "demonstrator" the test was commenced. Previous to becoming an interesting onlooker, the engineer went the rounds of the different departments and advised them to be prepared for an early shut down. The manager and salesman stood quietly by as the coke specialists loaded the hopper with the recent arrival, no particular attention being paid to the size of the lumps that were thrown in. The travelling grates continued their regular course, automatically carrying the three inch layer of slack coal from the hopper to the fire chamber. The time soon arrived however, when the last of the slack coal reached the bottom of the hopper and in a very brief space of time the pressure gauge, which had been registering 100 lbs. per sq. in., gradually began to fall, so that in a few minutes the hand was pointing to 50, with the foremen of the machine departments inquiring as to the failure of the power.

As invariably happens, the practical man was at once approached for advice, when it was discovered that the coke had failed to find its way through the three inch opening, and the back half of the grate was bare of fuel, the cold air rushing through and cooling off the boiler shell. The coke was emptied from the hopper and spread on the concrete floor—all over the boiler room—and hammers were brought into play to reduce the lumps to a size that would pass through the openings of the mechanical stoker. In the meantime the bed of the fire was put in order and a fresh supply of slack placed in the hopper. When all was again ready, the coke demonstrator—still optimistic—took the leading role, and his assistants filled up the hopper with a supply of small coke. However, the result was little better than the preceding one; for while the coke passed through the opening and followed the bituminous and hard coal slack along the grates, it failed to ignite when reaching the fire chamber, and as soon as the air struck the thin open layer of coke, the rush of cold air prevented the back creeping of the fire that is necessary in the successful operation of this particular type of mechanical stoker. It was a very disappointed but wiser salesman that ordered the coke back to the bunkers and its subsequent removal next day.

## A PISTON DOES STOP AT REVERSAL

By W. Fletcher Shepherd

IN his revival of this time-honored controversy in the December 6th issue Mr. R. Hamilton attempts by an ingenious argument based on Euclid's definition of a line to prove that a piston—theoretically—does not stop at reversal. Euclid's definition of a line as having length but neither breadth nor thickness is now, however, regarded as insufficient for modern analytical mathematics. According to the modern mathematical conception a line is the trace or path of a point moving in space or in a plane and its breadth and thickness are infinitely small as compared with its length.

That this conception is based on sound reasoning a moment's consideration will show. A point on a body moving along any path or line must pass through a multitude of points so that the line itself is composed of an infinite succession of points. If then a point has no dimensions at all no progress could be made along the line since if nothing be added to nothing the sum is nothing no matter how often the process be repeated.

Now it appears to the writer that the piston problem can be very simply settled by a close observation of the pin joining the connecting rod to the crank. The path of the crank pin center is a circle and in a well balanced engine the crank pin moves around its entire circular path with practically no lost motion. Its reciprocating motion, however, in the direction parallel to the piston axis varies in acceleration and speed from a maximum at the middle of the piston stroke to zero at each end of the piston stroke. We also observe that at each end of the piston stroke the crank pin centre crosses the piston axis at right angles and can therefore at that instant have absolutely no movement in either direction along that axis. The breadth of that axis may be infinitely small and the time consumed in crossing it infinitely short but the essential fact remains that there is an instant when the crank pin has absolutely no movement in either direction along that axis and this is true irrespective of the speed of the engine.

Now since the crank pin is linked to the piston the latter also at that instant can have absolutely no movement in either direction along its axis and since these are the only directions in which it can move the piston must therefore for that instant be at rest.

## HIGH-SPEED RAILWAYS AFTER THE WAR

THE subject of rapid transportation and its possible developments in the near future were the subject of an address by Chalmers Kearney before the Society of Engineers last month, in the course of which he pointed out that rapid transit for passengers and goods was of paramount importance in the economic life of a nation.

The essentials of a successful high-speed railway were enumerated by the speaker as follow:—

It must eliminate oscillation;

It must allow of the use of simple points and crossings;

It must be reasonably cheap to construct;

It should be capable of being built coincident with existing lines, and through existing tunnels;

It should be capable of being used as a surface, elevated, or tube railway;

It should not depend for the stability of its cars on moving mechanisms (such as gyroscopes);

It should not concentrate the stresses due to centrifugal force and side wind pressure on one rail.

The existing lines as well as various systems proposed by inventors from time to time do not fufil all these requirements, and it was to solve the problem presented and meet these points that the Kearney high-speed railway was designed. Details of track construction were given and the ample margin for safety illustrated. For practical purposes Kearney high-speed trains will be secure from derailment under all conditions. Pictures of the first full size passenger carrying car were exhibited. The car is "streamlined" to reduce air resistance at high-speeds and ball bearings of an improved type are used. As is well known the Kearney system employs a single rail to carry the weight of the trains and a second overhead guide rail to maintain equilibrium. The mechanical advantages of this method were fully described by the author. Simplicity in design has been achieved and the cost of the overhead structure is actually less than in the case of that for the electric transmission wires on the Brighton Elevated Electric. Future Kearney lines would cost much less to build on account of the steeper gradients which may be employed which will permit of large reductions in embankments, cuttings and tunnels. Bridges would also cost much less owing to the concentration of the load on to one deep plate girder.

### Speed Possibilities

As regards working, Mr. Kearney considered that speeds of 100 to 150 miles an hour would be economically sound with this system and showed how operating costs would be reduced. The abodition of oscillation and consequent concussion would greatly reduce the cost of upkeep of the tracks. In short, high-speed railways would not merely prove to be an economic advantage but a commercial necessity in the era after the war.

Speaking of underground railways, Mr. Kearney said that present methods left much to be desired. The four points for consideration in the construction of future underground lines were:—

To secure more convenient stations;

To reduce capital expenditure;

To obtain higher speeds;

To reduce operating costs.

The London Tubes were phenomenally slow owing to the lifts. They were also extremely expensive to build and to work. The Kearney system removed these disadvantages and secured all requirements. A recent improvement in the Kearney system is the design of a

"stepless" street level station. An in- [illegible] pavement on to the platform and into [illegible] hour would be reached in 23 seconds from the start. The train would then [illegible] the next station when it would run up a similar gradient which would bring it to a standstill without the destructive use of brakes. Such lines besides being vastly more convenient for passengers [illegible] great as on the present tubes. This means a corresponding reduction in the number of trains employed, reduced staff, lower working costs, higher wages and lower fares. The ventilation of such [illegible] perfect.

## MECHANICAL DENTISTRY COURSE FOR DISABLED SOLDIERS

Dental mechanics is one of the little known trades in which returned men are manifesting an interest when they return to Canada incapacitated for their former occupations. The vocational training of the Military Hospitals Commission has been called upon to make provision for it in their re-education courses.

The work requires mechanical skill and a fine eye for detail and holds, through its demands for fine work and ingenuity, an unusual interest for the able man who [illegible] incapacitated for heavier work.

In France a school of dental mechanics has been established for disabled soldiers by Dr. Quintero of Lyons, and a large class of veterans is under instruction, but the Military Hospitals Commission has made arrangements for Canadian men to take the work in established schools here. The work pays well and a skilful man can become an efficient workman in eight months.

The course has been granted to several soldiers, one a Montreal man who before he enlisted was a very successful salesman, drawing a good salary. He suffers now from an injured hip and cannot walk without pain. He must have work at which he can sit.

Enquiry into his past showed that his father had been an inventor and that he too inherited a certain ingenuity with mechanical things. He had demonstrated this in helping the dental officer on active service, and so an eight months' course was granted him by the government. His progress in the first month gives promise of great success.

## COMMERCIAL ARTS OPEN TO VETERANS

SOLDIERS in the Toronto Technical School come from all parts of the Dom- [illegible] of new vo- [illegible] tions, but none is more interesting than [illegible] in the

Men with talent whom fortune granted only a meagre means of expression before the war are being given opportunity to further their ambitions and many of them will go back into the industrial world better off, one might say, for their injuries. This is true of three men now under instruction who are making remarkable progress at their new occupations.

Pte. M. J. Claire was a stone carver before he enlisted. He went overseas, and was so wounded that such work was out of the question. To make the most of his natural talent, a new work allied in some way to his previous experience must be found. He turned to industrial clay modelling. Here his artistic ability will enable him to become competent to command a splendid salary.

### Paralysed Designer

A veteran by the name of J. R. Champion whose pre-war occupation was house painting is now engaged in stencil designing. Graduated from out door painting he is now being qualified to do the more detailed and better paid work of interior decoration. He is making good and turning out fine work in spite of the fact that he is paralyzed partially in both hands.

The Military Hospitals Commission, in arranging these courses for soldiers, attribute a large degree of the success with which men so disabled as to require occupational re-education are being placed again in condition to earn a good livelihood to the care with which the courses are adapted to their previous experience.

## TORONTO FIRM BUILDS MOTOR LIFE-BOATS

SEVERAL large motor-powered lifeboats are now under construction at the Canadian Beaver Company at the foot of York Street. They are to be used on the Norwegian Government ships, which are being built at the Polson Iron Works.

The life-boats are 24 feet over all, with a beam of seven feet. They are being fitted with a 12 horse-power Foreman gasoline motor, and have a seating capacity of 30, and when loaded are expected to attain a speed of seven miles an hour. Fitted with two belts of cork 12 inches in diameter amidships and tapering off to nothing at bow and stern, they are absolutely unsinkable. The boats are also fitted for towing, and have the luxury of a canvas hood to enclose the whole cockpit. The frames are made of the finest white oak and are planked with cypress. Four pairs of oars are provided. The oak water-casks are aft, and the provision locker in the bows The fuel tank is amidships, and has a capacity for 50 gallons.

The Canadian Beaver Company is also constructing a number of life-rafts for the same ships, the tanks of which are made of regulation government copper, the frames of white oak, and will, in case of emergency, be taken in tow by the life-boats. The rafts are 8 feet by 10 feet, and have a capacity of 25 persons. The rafts are always carried loose on the decks, except in very rough weather, when they are lashed.

## EYE HAZARDS IN INDUSTRIAL OCCUPATIONS

A NEW book written by Gordon L. Berry, Field Secretary, National Committee for the Prevention of Blindness, with the co-operation of Lieut. Thomas P. Bradshaw, U.S. Army, formerly Technical Assistant to the Director of the American Museum of Safety, octavo, 150 pages, fully illustrated. Published by the National Committee for the Prevention of Blindness, 130 East 22nd Street, New York. Price, 50 cents.

In this volume the author reviews the chief industrial hazards to eyesight in the industries of the United States. Case reports illustrate each section, the special dangers are described and recommendations made for such changes of working conditions, or installations of protective devices, as have been found suitable for protecting workers. The book is most completely illustrated.

The following section headings indicate the scope of the book: Statistics of eye accidents, chipping operations, machine operations, abrasive wheels, sand-blasting, "mushroomed" tools, riveting, radiations from intense light and heat sources, ultraviolet rays in illuminants, radiant energy in arc welding and in molten metal, metallurgic operations, glassblowers' cataract, infections, gauge glasses, acids and chemicals, treatment of acid burns, industrial poisons, removal of dangerous fumes, vapors and gases, spray process hazards, methyl alcohol, bottling accidents, mining and quarrying, agricultural hazards, goggles, garment trade hazards, industrial lighting, the safety movement.

These subjects have been treated not so much in the way of a technical manual for safety engineers, but rather in a general informative way for the information of the average manufacturer or layman who is seeking information of this nature. Descriptions of many of these hazards have been included heretofore in publications covering the complete field of industrial accident prevention, and where discussion of preventive measures would be repetition, the author has referred his reader to the chief of those sources where such detailed information might be secured, if desired.

The book is the most complete compilation of material relating solely to the prevention of eye accidents that has been published in this country. Inasmuch as there occur annually in the United States alone nearly 200,000 eye accidents, from which many cases of total blindness result, it would seem that there is need for further attention to this important subject.

## TECHNICAL WRITING AN AID TO ADVANCEMENT

THE majority of mechanics, when urged to express in writing their ideas, views and specific knowledge of things mechanical, postpone the fateful day with a variety of excuses. Inability to express themselves clearly, lack of time, lack of subjects to write about—these three reasons are put forward without hesitation when a few minutes' consideration would show that in fully 90 per cent. of the cases there is no foundation for even one of them.

It is not overstating the mark to say that one out of every eight or ten machinists and probably one out of every five toolmakers has sufficient knowledge, i.e., experience and education, to enable them to contribute real, live articles on questions of vital interest to many of our readers.

If dictaphone records could be taken of the various conversations and anecdotes which take place in the average tool room in connection with troublesome jobs and how they were overcome, the amount of latent knowledge gathered in a few days would surprise not only the parties themselves, but their employers also.

At the present time there are numbers of mechanics in the making—men who have started in munitions shops either through stress of circumstances or lure of high wages.

Despite recent and future changes in the machinist trade, the fascination which machine work has for many men has taken complete hold of them and brought to the surface an amount of mechanical ability which has lain dormant until awakened by opportunity.

Such men, although bred and trained to other trades, have had a natural liking for wheels, etc., and when circumstances compelled them to hire out as simple operators they at once got down to a working bearing at a speed far beyond that of the most ambitious apprentice.

Now, after extended experience and a fair knowledge of what a machinist can accomplish, they feel that their duty to themselves and their employers is to equip themselves mentally and materially to the best of their ability.

In helping others we help ourselves! The truth of this statement can be vouched for by any mechanic who can recall occasions on which he has helped a fellow worker out of a hole. Perhaps a certain tooling arrangement would not operate satisfactorily, too much chatter—if tightened up to suit, some other objection would arise—a case of gradual elimination of trouble until success is obtained. Such a procedure is of weekly if not daily occurrence in hundreds of shops, each case a problem in itself, and the solution buried in the depths of the tool room foreman's memory until jerked out again by some similar circumstance.

The idea itself represents no intrinsic value in dollars and cents to either the foreman or his employers, it is all part of the day's work, but just inasmuch as hundreds of these incidents are forgotten, so is the trade deprived of general knowledge and many individuals of information which they may ultimately have to dig up for themselves by arduous effort.

Handicraft, mechanical ability, skill in machine operation—call it what you will—such faculty is frequently born and most times developed, but the knowledge of how to utilize such accomplishment to the best possible ends can only be gained by experience and he who gives his experience to others gets it back one hundredfold.

The old bogey of trade secrets has been almost completely dispelled by modern science. Individual research along all lines of machine shop practice has evolved certain principles which are world-wide knowledge, results given freely to all who may look and listen. The successful application of such principles to daily problems is the business of the progressive machinist, and just as research continues to open up increasing fields for itself, so does the machinist's work suggest new angles of attack.

In recording, describing and incidentally criticizing his own work the present-day machinist, be he lathe hand or toolmaker, will find his knowledge of his own ability greatly increased, his confidence in himself increased, with, as many notable cases have shown, his responsibility increased, and last, but not least, the knowledge that in doing so he has helped others less favored than himself by opportunity or natural gift.

## BUYING COAL ON A HEAT BASIS

THE purchase of coal on a basis of contained heat units appeals to the engineer who is accustomed to judging the majority of materials on an efficiency basis. As a standard of value it is the only correct method of classifying fuels apart from types such as hard, soft, etc., each of which has individual characteristics rendering it more or less suited for specific purposes.

It is stated that since 1906 the $8,000,000 worth of fuel purchased annually by the United States Government has been bought on B.t.u. and chemical bases, and it is suggested that our own government might well adopt such a plan in buying over $1,000,000 worth of coal yearly. Where large amounts such as these are dealt with, the system is equitable as the producer must have a production large enough to allow inequalities of cost, etc., to balance up.

As the better grades get exhausted, they cost more to mine, and relatively may give the producer a smaller profit per ton than a lower grade easily mined coal which can be sold on the open market at ruling prices irrespective of its efficiency as a heat producer.

The root of ultimate trouble is the fact that coal is not a manufactured product and must be accepted as Nature made it. Perhaps when national fuel control is an accomplished fact, the manipulation of coal for by-products will enable a standard fuel to be made available which will possess a nearly uniform heat content and avoid many inconsistencies which would arise if the heat basis were adopted on a wide scale at present.

# Weather Aids Country in Its Fight Against Fuel Shortage

*Order Accepted in Good Spirit—Milder Weather Aids Movement*
*Steel Situation Continues Acute With Reduced Output*
*Metal Markets Quiet—Machine Tool Business Steady*

**The closing down of practically all industrial establishments over the week-end naturally disorganized business, but it was taken in good spirit in spite of the loss entailed. The necessity of the Fuel Controller's order was recognized and it is to be hoped that the saving in fuel justifies the drastic measures resorted to. Fortunately milder weather intervened which helped considerably in the saving of fuel as well as in moving cars from the border. The strictest economy in the use of coal is imperative in order to conserve available supplies and prevent, if possible, another period of "heatless days," and the loss which results from the decline in production of the factories. There have been no developments of importance in the iron and steel trade this week. Conditions have not shown any improvement although the milder weather will relieve the situation to some extent by permitting a heavier movement of coke and more favorable operating conditions at the furnaces and mills. No pronounced improvement, however, is looked for until next month when the output should show a big increase. The situation in the iron and steel trade in the United States continues acute on account of the traffic congestion and the output of mills and furnaces is still a long way below capacity. The scrap market is dull and prices unchanged. Business in scrap metals is quiet and is being adversely affected by the freight congestion. In the non-ferrous metal markets business has been quieter this week on account of the holidays. There is no improvement in the tin market and the scarcity of this metal is affecting a number of manufacturing plants. Lead is firm but antimony and aluminum have both declined. Copper is firm and unchanged. Machine shop supplies are in good demand at firm prices. Castor oil is practically off the market as it cannot now be obtained from England. The machine tool market is steady and fairly active. Deliveries in equipment from the United States are very slow on account of the heavy demand there.**

MONTREAL, Que., Feb. 9, 1918.—Conservation of fuel is the dominating feature of this week's industrial "activity." In common with the United States the Canadian Fuel Controller has found it imperative to adopt similar methods for the saving of fuel during this period of prolonged cold and unfavorable weather. In addition to the three days' closing that has been deemed necessary in many branches of industrial and commercial life, additional curtailment will be made in railway passenger service during the next three months to effect a further saving of fuel. To facilitate the result of the heatless days and increase the available supply of necessary coal nothing but food and fuel will be loaded as freight during the period of industrial suspension. This action, it is expected, will materially assist in the attainment of the desired purpose, as shunting requirements at other than main terminals will be practically eliminated.

### Steel

While the industrial situation at the present time shows a slight improvement over that of a week ago, the betterment so far has not been pronounced owing to the prevailing conditions restricting production. Following the action of the American Government respecting the measures adopted for the conservation of fuel, the authorities here have taken similar steps to relieve a condition rapidly becoming acute. The moderating of the weather previous to the enforcement of the order promised well for the better movement of coal on the severely taxed railroads, but expectations in this connection were not fully realized owing to the return of the stormy weather of Saturday adding to the difficulties of the transportation problem. The inability of plants to obtain delivery of sufficient raw materials for capacity production has materially affected the output, which at the present time is considerably less than that under normal conditions. Even with the forced curtailment resulting from the Monday closing of many plants in the States it is practically impossible for sufficient fuel and other commodities to be shipped in such quantities for the total relief of present conditions. Not only are the mills unable to obtain fuel and materials for production, but the movement of cars is so uncertain and stocks are piling up to such an extent that a return to normal will necessarily take some considerable time even when the freer movement of freight is possible. Until a prolonged spell of favorable weather is experienced the industrial activities of the country must remain more or less demoralized. Owing to the congested condition of all American railroads Canadian dealers and consumers have found it almost impossible to get reasonable delivery on material coming from the States. Ship plate requirements for Canadian-built vessels are still hard to obtain. Many of the local steel plants and other industries working on essential production have secured special permission from Ottawa to continue operations through the period of restricted activity. Steel for the manufacture of the American shells is very slow in coming, and those plants that have received contracts for these shells are greatly inconvenienced in this connection.

### Metals

General conditions throughout the metal trade remain unchanged, production being ample to meet the requirements for all essential purposes, although domestic interests are still suffering from insufficient supply. The feature of the week is the acute condition in tin that has developed a more serious tone from the recent action of the British Government and the sharp advance on the London market. Copper is more settled and trading steady. Spelter is quiet and firm. Lead is unchanged, but with an easier undertone. Antimony is steady, while aluminum has weakened.

**Copper.**—The trade has become reconciled to the fact that no change will become effective regarding further price regulation until after the 1st of June at the earliest. This has had the tendency to remove much of the uncertainty prevailing last month, and in consequence the situation has become more settled and activity has returned to normal. While some dissatisfaction has been expressed because a higher price was not established, the general opinion appears to be that the present price is one very acceptable to the majority of producers and consumers. The American situation is still governed by the fixed price of 23½c. The local market is easier on a quieter demand, and quotations show a decline of 1c over that of last week, the price asked being 32c for lake and electro and 31c for castings.

**Tin.**—The seriousness of the present tin situation has been additionally emphasized by the further restrictions and regulations recently imposed by the British Government. Just what effect this will have on the securing of permits to ship tin to the States is not yet certain, but it is anticipated that increased difficulties will be experienced in this respect. It is possible that the recent action of the Imperial authorities has been taken to relieve the situation in America, but nothing definite has so far been announced. Information regarding shipments is often delayed for obvious reasons, thus making the situation more uncertain and unsettled. The advance on the London market during the past week has been approximately £8 per ton. New York has taken on additional

strength, and nominal quotations have shown a higher tendency, with trading practically suspended. Local dealers report a fair demand, with stocks declining and prices moving to higher levels, this week's quotation of 79c being an advance of 2c per lb.

**Spelter.**—Considerable annoyance has been felt throughout the spelter trade through the indifference of the American Government in regard to the fixing of a set price to regulate the sale of the metal. In the face of what has taken place in iron and steel and other metals the spelter interests feel that the War Industries Board have been negligent in this connection. It is the opinion of many, however, that definite action will not be taken, and the trade will continue to operate under the supply and demand created by an open market. The local situation is apparently showing strength, but dealers continue to quote the unchanged price of 10½c per lb.

**Lead.**—Apart from the Government activity, the situation in the States has not been marked by any particular features, and general conditions are of a quiet character. The trust price of 6¾c continues to be about ⅜c below that quoted on the open market. Lead is quiet on the local market, and the lighter demand has given the situation an easier tone. Dealers, however, continue to quote 9¾c per lb.

**Antimony.**—While a fair volume of business is being done, the market cannot be said to be active. A weaker tendency has developed in the States and New York quotations show a decline of ¼c per lb., the price quoted being 14c for Chinese and Japanese. The market here is steady, with dealers reporting unchanged prices, these being 18c per lb.

**Aluminum.**—While the general demand continues the increase in available supply has produced an easier market, some local quotations being as low as 55c per lb. A fair average quotation here is 56c per lb.

### Machine Tools and Supplies

Another week of comparative quiet has been experienced in the machine tool industry. Inquiries have been light and sales have been few, business reported being of a general character, with no marked demand for any particular class of equipment. The difficulty of obtaining delivery from points in the United States is still very pronounced owing to the abnormal requirements for industrial purposes across the line and the congested condition of American railroads. Conditions that have prevailed throughout the past several weeks, necessitating the restriction of production, has also affected the supply market, reflected in the marked falling off in the demand for general machine shop accessories. Despite this, however, the total requirements for present activities continue to be of an encouraging volume.

### Scrap

Unsettled conditions are the dominating feature of the old metal market, due to the uncertainty that prevails regarding the contemplated action of the American Government respecting the regulation of this business. During recent weeks the trade has been operating under considerable difficulty in the handling of scrap to and from the plants and furnaces owing to the shortage of cars and the inability of the railroads to take care of the enormous volume of freight that has accumulated during the severe weather. Under these conditions consumers have often been forced to curtail production for want of scrap materials. Owing to the fact that railroads will confine themselves to the loading of food and fuel dealers in scrap expect to have a very quiet week-end. Local quotations are unchanged, dealers preferring to hold firm at prevailing prices.

## Toronto

TORONTO, Ont., Feb. 12.—The industrial situation continues to be affected by the unfavorable transportation conditions although some relief is looked for as a result of the three days' suspension of industrial activity and also if the mild weather continues. With favorable traffic conditions much can be done during this week in relieving the freight congestion but no decided improvement is possible until the spring. The strictest economy in the use of coal is urgently enjoined by the Fuel Controller for by this means a great saving can be effected and probably further drastic measures obviated.

**CANADIAN GOVERNMENT PURCHASING COMMISSION**

**The following gentlemen constitute the War Purchasing Commission appointed by the Canadian Government: Hormidas Laporte, Montreal, chairman; George F. Galt, Winnipeg; William P. Gundy, Toronto. Thomas Hillier is secretary, and the Commission headquarters are at Ottawa.**

### Iron and Steel

There is no appreciable change in the situation in the iron and steel trade but the outlook has improved now that the severe weather has disappeared. If the mild weather continues there will be a heavier movement of fuel to the furnaces and steel plants, while operating conditions will be more favorable. Some weeks must elapse, however, before there is any decided improvement in conditions or material increase in output as stocks of fuel have become so low and transportation facilities so disorganized that it will be some time before conditions are even approaching normal. As a result of the falling off in production unfilled tonnage has consequently increased: The Algoma Steel Corporation reports that the situation is improving and that the company has plenty of business booked. Practically sold, the unfilled orders on hand at Dec. 31 representing 437,951 tons. Adequate supplies of raw materials are reported to be on hand, and enough coal has been secured to carry through until navigation opens. Blast furnace operations were interfered with during December operations.

The recent reports of the contemplated merger between the Dominion Steel Corporation and the Nova Scotia Steel & Coal Co. has brought to notice some interesting facts in connection with the progress of these two concerns, also the Steel Company of Canada, during the war period. The liquid position of the companies is the most striking part of the new conditions, and they show a remarkable reversal of form when contrasted with the situation as recently as five years ago. No doubt the steel boom is inflated, but the fact remains the companies have worked to such advantage, owing to capacity production, that their coffers are full to overflowing. Apart from cash surpluses, there has been a drastic writing off for depreciation which has probably left plant account at bedrock figures. All these factors serve as a guarantee for the future. Companies with complete plant units and an abundance of cash and ore reserves will have little cause to fear foreign competition when steel prices decline in peace times. And, furthermore, it is certain Canadian railways alone will have enough business to place to keep all the steel works running at profitable speed some time after peace is declared and when war orders cease.

The pig iron market continues more or less unsettled on account of the coke situation, although some relief is looked for concurrent with the improvement in the weather. The respite will probably be only of short duration so no permanent relief can be expected for some weeks. Canadian concerns have been in the market recently for pig iron in the United States but conditions across the line are anything but satisfactory. Steel mills and blast furnaces are making small headway in recovering the lost ground due to compulsory cutting down of production in the last few weeks through the breakdown of the transportation system and unfavorable weather. As a result of these conditions, Government plans for rushing production of ordnance and other war munitions have been badly interfered with. The situation is reflected in the unfilled tonnage report of the U.S. Steel Corporation for January. The unfilled orders of the Corporation on January 31 were 9,477,853 tons, acording to the monthly statement issued [illegible] Tons, an increase of 96,135 tons compared with the orders on hand Dec. 31st.

### Scrap Metals

The market continues dull with very little business passing. Traffic conditions are affecting the market, as it is almost impossible to ship any scrap. Supplies of scrap are accumulating and

when the freight congestion is relieved it is possible that prices will be easier due to increase in supply. Heavy melting steel and cast iron scrap are firm but copper and brass are easier but unchanged.

### Machine Tools

Little has been done in developments of importance in the machine tool market, this week. Business has been fairly active, with munitions equipment predominating. Machine tool builders in the States have been seriously affected by the fuel situation and maximum production is almost impossible. As the Government demand for machinery is getting heavier, private consumers are finding it a difficult matter to get tools. The output of the builders is sold up for several months in the case of some types and to more than a year in others. There is a good demand for second hand equipment.

### Supplies

A good steady business is reported by dealers in machine shop supplies. Prices generally are very firm with a higher tendency for a number of lines. On account of the great demand for leather prices of belting are very firm. English castor oil is practically off the market here as it is now impossible to get shipment of this commodity from England owing to the heavy demand for war purposes. An advance of 25c a barrel in the price of Pennsylvania crude oil to a new quotation of $4 was announced recently by the South Penn. Oil Co. Other grades were increased five cents. Local prices are holding very firm but are unchanged in the meantime.

### Non-Ferrous Metals

The closing down of so many industrial establishments has affected the market and business has been rather slow. The tin market continues nominal, otherwise prices have a weaker tendency, lead being the only metal to show any degree of strength. There is no change in the copper situation and none is expected as the market is regulated. Lead is a shade higher on account of the scarcity of this metal. The spelter market is dull and prices unchanged but both antimony and aluminum are weaker and have declined.

**Copper.**—The market has been quiet, but conditions are very strong from the point of view of the selling and producing interests as the need of metal is insistent and available supplies are very small. It is generally believed that copper can and will be produced at the mines in sufficient quantity to meet all requirements but there is some fear that the freight congestion may interfere with shipments of ore from the mines to the refineries. Local prices are unchanged, lake and electrolytic copper being quoted at 29c and castings at 28c per pound.

**Tin.**—Practically all arrivals of tin in the United States are being commandeered by the Emergency Fleet Corporation and Chinese tin is understood to be controlled by Japanese interests. There is no spot metal available and the shortage is becoming a serious matter to many consumers who are badly in need of tin. Tin quotations are entirely nominal at 80c per pound.

**Spelter.**—The market is quiet and very little interest is being shown in spelter. Stocks are ample for requirements and consumers do not appear to be anxious to do business.

**Lead.**—The scarcity of lead in the East due to traffic congestion continues. There is a fair demand for lead and but for the shortage, business would be more active. Locally lead has advanced ½c and is now quoted at 9c per pound.

**Antimony.**—The market has a weaker tendency and quotations are lower at 17c per pound.

**Aluminum.**—The demand for aluminum is light but there is little spot metal offering.. Aluminum has declined 8c and is now quoted at 52c per pound.

## Washington

WASHINGTON, Feb. 9.—The labor agreement entered into between the United States and Canada is regarded here as one of the most effective measures taken since the beginning of the war to make the industries of both the United States and Canada most effective. Under the plan worked out it is the opinion of officials of the Department of Labor that the labor resources of the United States and Canada will be virtually pooled and all labor competition will be wiped out.

### Labor Agreement

Under the terms of agreement there can be no shifting of labor from the United States to Canada or vice versa, without the permission of the two governments interested. This measure will protect Canadian manufacturers from the inroads made on their labor supply by the higher wages offered by some manufacturers in the United States. On the other hand it is deemed a measure that will be equally favorable to the United States. For some time, according to officials of the Department of Labor here, there has been a general shifting of labor between the United States and Canada and this has resulted in disruption of the industries of both countries. Under the present agreement there must be mutual agreement by both governments before there can be any labor shifting so that there will be a virtual pooling of surplus labor. All fears expressed by industrial leaders that the plan might work to the disadvantage of the United States have been set at rest by the Department of Labor. Senator G. D. Robertson of Canada has been appointed as the representative of Canada to act as a member of the Federal Employment Board of the United States and protect the interests of Canadian labor and industry at all times.

### Shipping Board Activities

The United States Shipping Board is scheduled for another reorganization. Chairman Edward N. Hurley of the Shipping Board has not made public his plans of reorganization yet, but he has told the Senate Commerce committee which is investigating the shipping problem that he has plans for changes in personnel that will speed up the work of constructing an American merchant marine.

At the present time a concentrated drive for labor is going on in the United States with a view of securing adequate labor forces to carry on the work of the Shipping Board. George Piez of the Shipping Board is directing this great drive for shipbuilders and it is hoped that 250,000 ship constructers will be enlisted within a months' time. There are at present, Mr. Piez states, 713 ship ways in the United States and it will be necessary to carry on work in these ship ways twenty-four hours a day. In order to do this sufficient men are to be recruited to maintain three eight hour shifts in every shipyard in the country. In this connection it is declared that the recent labor agreement with Canada will work to the benefit of the United States. It has been suggested that some Canadian labor may be borrowed from Canadian shipyards and put at work in yards in the United States. Negotiations to this end have already been started. Whether or not the surplus labor among the Canadian shipbuilders is sufficient to allow them to give any large number of workers to the shipbuilders in the United States, it is hoped that some experienced Canadian shipbuilders can be secured in order that they may be made "leaders" for raw labor, which has been recently recruited.

### More Trade Prohibitions

Strict prohibition on imports and exports of the United States will be the next drastic step taken by the United States Government. It is generally understood that within a few days President Wilson will issue a proclamation in which he will set forth drastic regulations of the imports and exports of the United States. The step is taken in order that every possible bit of shipping space may be reserved for the transportation of war supplies. It is understood that all non-essentials will be prohibited, both as imports and exports. Detailed instructions will be given as to what are considered essentials and what are non-essentials. It is generally believed here that some agreement will be made with the Canadian Government whereby the full terms of the proclamation will not be extended to trade between the United States and Canada. Inasmuch as much of the trade between these two countries does not involve the use of any shipping which might be used for trans-oceanic cargoes the effect of the prohibition would be to put a damper on trade which has no interference with the problem of shipping war supplies across the Atlantic.

The fuel situation in the United States has become somewhat relieved during the past week. It has reached a state

where the order issued by Fuel Administrator Garfield, closing down factories on Mondays, has been revoked in as far as it applies to the Southern states. Railroad congestion is gradually clearing and there is a hope that the closing order may be gradually revoked until all the industries of the United States will be unrestricted before April 1, when the order finally ceases to operate.

The question of shipping space still remains the most important question confronting officials of the United States. An agreement reached with the Allies for the pooling of all shipping space and placing the control of all bottoms in the hands of a central committee is looked upon as one measure which can be counted upon to bring maximum efficiency to shipping.

### Executive Reorganization Due

President Wilson has asked Congress for power to reorganize the executive departments of the government. This measure will probably fail to pass Congress, but it is generally taken in Washington as an indication that a general reorganization is about to come, which will place the industries of the nation more fully in the power of the government. President Wilson has steadfastly refused to countenance proposals for the establishment of a Director of Munitions, but it is generally conceded that steps will be taken shortly which will place the war industries of the nation under a more central head. It is regarded as a possibility that the present War Industries Board which has only the power of advice now may be given some real authority by legislation.

Ninety-two commercial trucks valued at $111,038 were exported to Canada during December, 1917. The number exported during the calendar year 1917 was 882, valued at $1,075,750. The number of pleasure automobiles exported in December last was 1,852, valued at $1,318,786. The number exported during the calendar year 1917 was 16,438, valued at $12,401,705.

## New York

NEW YORK, Feb. 9.—Large orders for machine tools are being placed by the Government for arsenals, private ordnance plants and other factories producing war munitions. The buying this week follows as a result of the vigorous campaign waged by the machine tool section of the War Industries Board, the chief signal officer of the Army and the Navy Department. Unfortunately, the army and navy still appear as competitors in purchasing war material. Apparently there is race between Army and Navy Department officials to locate machinery needed as a step toward commandeering, if necessary. The War Industries Board has demanded a list of the purchasers of certain types of tools in the last twenty years. The machine tool builders are furnishing the information. Dealers in second hand machinery also are instructed to furnish lists of tools which they may own or which may be located for Government inspection. The chief signal officer of the army has made requests for price lists and discount sheets covering tools catalogued by various manufacturers, while the Navy Department is demanding a list of all the machine tools held in storage in New York. It will be recalled that only a few weeks ago the Government put out a hurry call for 1,000 machine tools and it is understood that while most of these are wanted for ordnance plants in this country, other heavy purchases of tools will be made for export to France.

### Aviation Activities

One interesting development, is the cancellation of the contract for 500 Liberty motors, given to the Duesenberg Motors Corp. of Newark, but, as a substitute, a contract for 2,000 Bugatti aviation motors has been given to the same manufacturers; as a result of these orders the Newark plant will be doubled in capacity, requiring the purchase of more machine tools. In this connection it is also of interest to know that the Canadian plant of the Willys-Overland Co. will soon make substantial deliveries of the "Sunbeam" aeroplane engines which heretofore have been manufactured almost entirely in Great Britain. So great is the demand for various types of aeroplane engines that additional large contracts are expected to be placed in this country as well as in Canada.

Aviation work is absorbing the attention of all of the Allied Governments to an unusual degree at the present time. The United States Government is preparing to place contracts for 65,000 tons of structural steel for hangars in France and the British and French Governments are seeking to place orders for 1,000 hangars requiring 35,000 tons of steel. All of this material will be purchased in the United States. Five fabricating shops are ready to fabricate the steel shapes but four or five of the largest structural mills have refused to bid upon the contracts for plain material for shipment in the time required by the Government. The chief officer of the signal corps of the army called for the fabricated steel required for 2,000 hangars in sixty days. Allowing sufficient time for transportation and fabrication would mean that the shapes would have to be rolled by the mills in two or three weeks. Under present conditions of reduced operations and demoralized traffic, as well as the relatively small number of mills prepared to roll light sizes at once, the material cannot be furnished in the time specified by the Government. The structural mills are already rolling large tonnages of shapes for the Government. In time, however, all the needs for aviation work can be met.

### Steel Output

Numerous manufacturers of guns, gun mounts, projectiles and engines in the Eastern territory are buying small lots of shop equipment to take care of additional orders placed by the Government in the last ten days.

To-day the U.S. Steel Corporation reported unfilled orders on hand Jan. 31, 9,477,353 tons which is an increase of 96,135 tons over unfilled orders carried at the end of 1917. The deplorable condition of transportation and the unfavorable weather made it impossible for the corporation to operate more than 45 to 50 per cent. of total capacity last month. Upon this basis, the output of ingots was approximately 900,000 tons, indicating production of 675,000 tons of rolled steel products. Shipments are estimated to have been 600,000 tons and orders taken therefore would be a little less than 700,000 tons.

## Pittsburgh

PITTSBURGH, Pa., Feb. 9.—This is the fourth day of mild weather, 40° to 50°, after 10° below zero was touched Tuesday. Barring the possibility of another cold snap, transportation conditions should improve rapidly, and with that improvement there must be a sharp increase in the production and consumption of steel. Thus far there has been no noteworthy improvement in traffic movement, though the experience of some shippers has been less unsatisfactory in the past day or two.

### Effect of Railroad Block

How greatly the railroads have been blockaded is being emphasized by concrete data now being received. Iron ore shipments from Lake Erie docks in January were only 199,091 tons, against 686,227 tons the preceding January, and leaving 10,069,592 tons on dock, whereas by the opening of navigation in April there should be only a very few million tons on docks.

Pig iron production in the United States in January was at the rate of only 28,750,000 tons a year, when the capacity is between 42,000,000 and 43,000,000 tons. In 1916 production was 39,400,000 tons, and many new blast furnaces have since been completed. Production since the 1st of February has been at the rate of less than 25,000,000 tons, probably considerably less.

Shipments of Connellsville coke in the week ended Feb. 2 were 228,539 tons, against an average of 420,000 tons in 1916. On account of completion of many by-product plants not as much Connellsville coke as formerly is needed; but it would require close to 375,000 tons a week to supply the furnaces still depending on Connellsville coke. The production of pig iron is below its normal proportion to the coke supply, as irregular working of furnaces increases the coke consumption per ton of pig iron produced, this frequently mounting to 3,000 pounds, against a normal of about 2,200 pounds.

Estimates are that during January the shipments of steel mills in the Pittsburgh, Youngstown and lake front districts averaged between 50 and 60 per cent. of capacity, while since the first of this month the average has probably been not over 50 per cent.

There are railroad embargoes against nearly all important steel consuming points, and permits are required, these

some classes of war material. Cars are secured first there may be demurrage while the permit is awaited. If one must wait for cars the permit sometimes expires. Of the shipments made since the first of the year fully two-thirds have been of war material, the remainder being ordinary commercial steel. Shipments for export are very light, as there is already much material at seaboard awaiting shipment.

### Steel Corporation Business

At noon to-day the United States Steel Corporation reported its unfilled obligations at the close of January at 9,477,853 tons, indicating an increase during January of 96,135 tons. This [illegible] of 484,612 tons in December, a decrease of 112,569 tons in November, and decreases averaging 575,000 tons a month during the five months preceding. The December increase was due almost wholly to the booking of contracts for sheets and tin plates for the first half of this year. Excluding altogether the item of sheets and tin plates, the corporation's bookings exceeded the shipments by about 75,000 tons more in January than they did in December, but the shipments decreased about 250,000 tons, as it is estimated the corporation's shipments were about 80 per cent. of capacity in December and 60 per cent. in January. The bookings in each month were chiefly of war material.

### Record Exports

In December, the eleventh month of ruthless destruction of merchant shipping by German submarines, the iron and steel exports of the United States made a new record at 656,044 gross tons, breaking the previous record of 643,767 tons made in September, 1916. The calendar year total for 1917 is over 6,200,000 tons, a gain of 100,000 tons over 1916. The largest item in the December exports was 204,555 tons of ingots, blooms, billets, etc., this being chiefly shell steel exported to the Allies abroad. Next came 78,571 tons of steel bars, doubtless also steel for making the smaller shells. Pig iron exports were unusually large in December, amounting to 64,727 tons, against 24,140 tons in November.

### Market Prospects

There is not what can really be called a market at present, nor has there been one for several weeks past. Everything is against there being any buying or selling, except, of course, as war business arises. The average buyer or seller is quite indisposed to enter into new engagements in present circumstances. The great majority of buyers have large tonnages due them, on which deliveries are well behind-hand, while at the same time the consuming operations of buyers have been interfered with as much by traffic conditions as have the operations of producers. The buyer does not know how much material he is going to be able to consume, and the seller does not know how much material he is going to be able to produce. A rough estimate would be that since the first of the year shipments of steel from mills have represented at the outside 60 per cent. of capacity—40 per cent. war steel and 20 per cent. commercial. A month hence the mills may be producing at 80 per cent., 100 per cent., or still at only 60 per cent. The consumer, who has been receiving steel at only 20 per cent. of productive capacity, may be offered 40 per cent. and not need it, or he may require 60 per cent. and not be able to get it.

All sales, except export sales not of war material, must carry a proviso that the price is to be readjusted to any new Government price that may be made as to any shipments made after March 31. What Washington is disposed to do as to revision of the set prices against that date no one has any definite inkling, and very likely there are no well-defined ideas in Washington on this subject. Conditions may be altogether changed by that time. Only a very few weeks of mild weather should put the railroads in shape again, and then a whole new market situation would be built up, with greatly increased production and increased consumption, perhaps as much increase in the latter as in the former, but more probably not as much. The railroads have not permanently broken down. While the traffic movement in the past two or three months has been extremely poor, the returns of freight movement for October, just compiled, indicate movement in that month at the rate of about 422,000,000,000 ton-miles a year. In the fiscal year ended June 30, 1916, the record fiscal year, the movement was 343,000,000 ton-miles. If the October rate of movement were restored and the iron and steel industry were given simply its former share of the total railroad service it would have ample facilities, so far as the movement of raw and finished is concerned, to operate at its full capacity. Thus the traffic movement will furnish the key to the iron and steel market when one is developed again.

## WAR INCREASES DEBT OF CANADA

RETURNS compiled by the Finance Department, at Ottawa, show that Canada's total gross debt on Jan. 31 was $1,994,563,746,32, as compared with a total gross debt of $1,226,185,543.53 on Jan. 31, 1917. Total assets amounted, on Jan. 31, to $997,034,539.05, leaving on that date a total net debt of $997,529,207.28. Between Dec. 31, 1917, and Jan. 31, 1918, the net debt increased by $21,100,703.10.

War expenditure during January amounted to $16,606,176, or a total during the ten months' period of $188,355,015. War expenditures during January, 1917, amounted to $24,074,932. War expenditures during the corresponding ten months' period of the previous fiscal year totalled $194,304,681.

Revenue during January showed a decline as compared with the figures for the same month last year. In January, 1918, it was $17,881,384; in January, 1917, it was $21,047,216. For the ten months' period, however, it shows an increase. Up to Jan. 31, 1918, revenue was $208,540,755; up to Jan. 31, 1917, it was $187,903,565.

## GOVERNMENT PLACE ORDERS FOR SHIPS

FABRICATION and assembling of materials for the first of the fleet of merchantmen to be built by the Dominion Government has been commenced, and a similar work for two other vessels will shortly be undertaken. The first ship, which will be a steel steamer of 4,350 tons burden will be laid down at the Canadian Vickers yard at Montreal. A second of 8,200 tons will follow at the same establishment, and, it is expected, a contract for a third ship of 3,800 tons will soon be made with the Collingwood Shipbuilding Co., which has a vacant berth in its yard. It is hoped that the ships to be built at the Vickers yard will be in commission by September next.

The Government's shipbuilding programme contemplates the laying down of the keels of some forty ships to June, 1919. Of the number, four of 5,000 tons and six of 8,200 tons are to be built on the Pacific Coast. All the vessels, however, are intended to relieve the shortage on the Atlantic and to ply there while the war continues.

Arrangements have been made whereby the Government is assured of a supply of ship plates and steel materials for its shipbuilding programme to June, 1919. Orders for steel for the Canadian Government will, it is understood, be placed by the United States' Purchasing Commission with various steel companies in that country. The Canadian Government, which, by the arrangement will be assured of securing material at as favorable prices as possible, will then make contracts with reference to deliveries and other features of the purchase agreements.

## WAR PURCHASING COMMISSION

AN order-in-Council, passed on Feb. 7, extends the functions of the War Purchasing Commission to purchase for all departments of the Government, whether connected with the prosecution of the war or otherwise. The only limitations are with respect to supplies of small value which may from time to time be urgently required at points distant from Ottawa, purchase of supplies for the Government system of railways, and in the case of purchases where the provisions of the new order cannot be enforced, "without detriment to the public interest."

"As far as practicable," it is provided further, "tenders shall be called for in respect of all contracts and purchases to be made by or under the authority of the commission, and the purchase shall be made from and the contracts given to the lowest tenderer."

The commission is to keep a systematic record of all business transacted and to make an annual report to the Governor-in-Council containing a statement of all contracts and purchases mde.

# Thread Accuracy

Are you satisfied with your threads? Are they all you desire? Do you wish to get better results?

That last question interests us vitally. Our Self-Opening Automatic Die Head will chase your troubles. Its quick release feature not only insures the cutting of the thread to a given point every time, but permits cutting right to the shoulder where required.

Our booklet will tell you about other features.

# INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News

## ENGINEERING

Three Rivers, P.Q.—The St. Maurice Foundry Co. are erecting a brick extension to their factory.

Vancouver, B.C.—White Brothers, of Bay City, Mich., propose erecting a pulp mill at Beaver Cove on North Vancouver Island.

**Brantford, Ont.**—Immediate Hydro power for Brantford Township has been promised the council of the municipality by Engineer Gaby, of the Ontario Hydro Commission.

**Toronto, Ont.**—The Ontario Wind Engine & Pump Co. has taken out a permit for the erection on the corner of Atlantic and Liberty Avenues of a steel and iron silo factory to cost $4,000.

**Montreal, Que.**—The Gillette Safety Razor Co. will enlarge its plant to five times the present capacity. The addition will cost about $750,000, and $180,000 worth of new machinery will be installed. The plant will have a capacity of 800 razors and 10,000 dozen blades a day.

**Toronto, Ont.**—Plans and specifications were ordered to be prepared at a private meeting of the transportation commission for a modern car factory to be used by the city when the street railway is taken over. It was also decided to prepare for the purchase of 250 new cars for delivery in September, 1921.

**Owen Sound, Ont.**—J. H. Cole, of this town, has organized a company under the name of the Great Lakes Steel Corporation to manufacture machine screw products and nuts. A site has not yet been purchased but the company has been incorporated with a capital of $1,000,000. J. H. Cole, 20 King street east, Toronto, is interested.

**Nanaimo, B.C.**—The Nanaimo Gas Co. has taken over the Nanaimo gas works, with W. W. Lewis in charge. Plans are already in hand for the improvement of the gas works on an extensive scale, which will place the works in a first-class condition. The plant that will be installed will be up-to-date in every respect and will be able to fill the wants of the city.

## GENERAL

**Toronto, Ont.**—The city architect has issued a building permit to R. Thompson to erect a brick factory, east side of Dundas street west, near Glenlake avenue, to cost $5,000.

Vancouver, B.C.—A new and important [illegible] of the Dominion Canners, Ltd., of Hamilton, Ont., are consummated. Three sites here are now under consideration of the directors of the company, who are personally looking over the ground with a view of establishing their second plant in British Columbia.

**Toronto, Ont.**—Two whole townships, estimated to contain millions of tons of peat, have been set aside by the Ontario Government with a view to having them developed as a source of fuel for the province. The two townships are Hanna and St. John, lying on either side of the T. and N. O. railway, immediately south of Cochrane. In these townships, unsuitable for cultivation, examination has shown that the deposits of peat range in depth from six to forty or fifty feet in some places.

## MUNICIPAL

**Mitchell, Ont.**—The Town Council are contemplating installing a gasoline engine and pump.

**Kelowna, B.C.**—The city council will purchase a motor-driven chemical engine for the fire department.

**Brandon, Man.**—The City Council contemplate installing a new pumping plant at the municipal waterwarks.

**Port Colborne, Ont.**—The Town Council contemplates the installation of a waterworks pumping plant and equipment.

**Hamilton, Ont.**—The city will reopen negotiations with the United Gas & Fuel Company in an endeavor to have a company build a coke oven here. The controllers unanimously agreed to take above action.

**Kingston, Ont.**—The City Council contemplate purchasing a motor driven pump and hose truck, estimated to cost $14 600 and a motor driven ladder truck to cost $7.000. A by-law will be prepared authorizing the purchase of this equipment.

**St. Thomas, Ont.**—The City Council propose to make considerable improvements to the local gas works including a new unloading and coal passing system, a more modern system of retorts, a new gas exhauster, an ammonia pump, etc. A new manager will be appointed.

**Brockville, Ont.**—There are extensive peat fields adjacent to Brockville, which, if developed, would supply a want in the fuel shortage. Local interests have expended much in drainage and experimenting with drying processes without any material results. The Town Council is now petitioning the Ontario Government to take over the project.

**Winnipeg, Man.**—At the meeting of the Greater Winnipeg Water District last Thursday afternoon, on learning that C. G. Anderson, owing to the alleged delay in granting the contract for the gate house and intake at Waugh, refused to do the work, Controller Wallace, seconded by Controller Cockburn, moved that the contract be granted to the next lowest tenderer, whose price was $97.000, while Anderson had tendered for $90,000.

## BUILDING

**Ottawa, Ont.**—It is understood that plans are now being prepared for a new nine-storey government office building to be erected at the south-west corner of Queen and O'Connor streets, on the site now occupied by the old fisheries exhibit building. It was announced a few days ago that the erection of such a building was under consideration, but it was not stated what site had been chosen.

## PERSONAL

**James S. N. Dougall**, president of the Dougall Varnish Co., Montreal, died on Feb. 2, at his residence, 102 Fort street, aged 64.

**M. J. Beatty**, of Beatty Bros., Fergus, Ont., has been elected a director of the company. He succeeds the late G. P. Scholfield.

**Alexander R. Milne**, marine engineer, known all over the Great Lakes, died at Kingston, Ont., on Feb. 6, after two days' illness. He was about 75 years of age.

**W. H. A. Fraser**, of Fraser & Co., and director of the Hull Power Co., died at his home in Ottawa on Feb. 4. Mr. Fraser was born at Westmeath, Ont., in 1863.

**E. J. Babbit** has been appointed chief clerk of the Montreal Locomotive Works, in place of W. C. Stagg, who has resigned to accept a position in the United States. Mr. Babbit was previously assistant to Mr. Stagg in the same office.

**Lloyd Harris**, president of the Russell Motor Co., who has been associated with the British War Mission in Washington for several months, has been appointed chairman of the Canadian War Mission in that city.

**Lieut.-Col. George A. Walker, R.E.**, formerly of Kingston, Ont., has been placed in charge of all British railway construction works in Palestine. He is a graduate of McGill, and spent some years as a railway engineer in British Columbia.

**J. H. Bertram**, collector of Customs for the Port of Toronto, who has been acting collector for the Port of Montreal during the past year, since the retirement of R. S. White, was given a cabinet of cutlery last Friday by the officials and employees of the Montreal Customs House. Mr. Bertram is leaving to resume his duties in Toronto, having been relieved by the appointment of Ald. W. S. Weldon as collector here.

**C. C. Curtiss**, successor to E. L. Milliken as manager of the Cape Breton Electric Co., has arrived in Sydney, N.S., and will immediately take up his new duties. Mr. Milliken leaves early next week for Houghton, Mich., where he will manage another branch of the company's

Canadian Agents: Williams & Wilson, Ltd., Montreal; The A. R. Williams Machinery Co., Ltd., Toronto, St. John, N.B.

# TRADE GOSSIP

The Sorel Shipbuilding & Coal Co., of Sorel, Que., has changed its name to that of Sorel Shipbuilders, Ltd.

**Contract Let for Concrete Ships.**—A contract for ten 3,500-ton concrete ships has been let by the U. S. Shipbuilding Board to the Ferrar Concrete Shipbuilding Corporation, of Redondo Beach, Cal., the first to be delivered within six months and the balance in a year.

**U. S. Steel Corporation Unfilled Orders.**—Unfilled orders of the U. S. Steel Corporation on Jan. 31 were 9,477,853 tons, according to the corporation's monthly statement issued a few days ago. This is an increase of 96,135 tons, compared with the orders on Dec. 31.

**The Canadian General Electric Co.** has secured the contract for the entire electrical equipment of the Bennett-Martin Asbestos and Chrome Mines at Coleraine, Que. The Canadian Wire & Cable Co. of Toronto, will supply the wire for the transmission system.

**The Canadian Car & Foundry Co., of** Montreal announce that they have opened an Ontario office at 303 Royal Bank Building, Toronto, under the direction of G. F. Richmond Junr. By this means the company will be in a position to look after the requirements of their Ontario customers by resident representation in the province.

**More Articles Not to be Exported From U. S.**—Additions made last Sunday by the War Trade Board, Washington, to its conservation list of materials which may not be exported to any country except under license include the following commodities: "Plate rolling mills, open-hearth blast furnaces, steel furnaces, rubber and all commodities containing rubber."

**Ford Plant Builds Submarine Chasers.**—The keel of the first of the super-submarine chasers being constructed at the Ford motor plant at Detroit was laid last Friday, Secretary of the Navy Daniels announced. It is expected that one of the vessels will be finished every day as soon as operations are in full swing. Several scores of the boats have been contracted for by the navy.

**Fire Losses in January in Canada.**—The "Monetary Times'" estimate of Canada's fire losses during January, 1918, is $2,688,556, compared with the December, 1917, loss of $5,144,100 and $1,918,660 for January, 1917. The total number of fatalities as the result of fires in January, 1918, was 28, which is the greatest number of fire fatalities in January for ten years.

**Must Load Cars to Full Capacity.**—[illegible] by any Canadian railway of freight for overseas export unless the cars are loaded to full cubic or weight-carrying capacity was issued last Friday by the Canadian [illegible]

of the Grand Trunk and chairman of the board, said that appeals to the public spirit of shippers had brought good results in combatting the car shortage.

**Kingston, Ont.**—Lieut. J. Werdon Edwards, son of Dr. J. W. Edwards, M.P. for Frontenac, who is serving with the Royal Flying Corps at the front, has invented an appliance for keeping aviators warm. His invention consists in equipping the aviator's clothing with wires through which he introduces an electric current generated from a motor driven by the airplane engine. The invention is being rapidly applied to all the machines in the Flying Corps.

**License Required for Export of Scrap From U. S.**—The United States War Trade Board calls attention to the fact that the exportation of scrap iron or steel requires an export license, and that any shipper who exports under any different classification (such as second-hand rails, car wheels, etc.) any articles manufactured of iron or steel which are exported for the purpose of being scrapped at destination is guilty of false declaration and is subject to such penalties therefor as the law provides.

**Steel From Sudbury Ores.**—A report has been prepared describing some tests carried out at the plant of the Canada Cement Co. of Montreal on a process for making steel direct from Sudbury ores. A high-grade alloy steel is being made from ores containing iron, nickel, and copper. The report claims certain advantages for the steel, one being that it is practically entirely made from Canadian materials. It has passed certain British Government tests, and is also being used commercially to a limited degree.

**Joint Commission to Prepare Report.**—The International Joint Commission created by Canada and United States in 1911 to consider the developing of water-power and securing adequate sanitation in rivers and streams jointly controlled by the two Governments met in New York on Feb. 4 to prepare its final report which will be submitted to the Dominion Parliament and to Congress. The text of the report, it was announced, will not be made public until it has been approved by both governments.

**Lake Superior Corporation Affairs.**—In a letter to Lake Superior Corporation stockholders, Secretary Taylor says: "Practically the entire steel output for 1918 is now sold, the unfilled orders on hand at December 31 representing 437,951 tons. Adequate supplies of raw materials are now on hand, and enough coal has been secured to carry through until navigation opens. Blast furnace operations were interfered with during December operations. We believe, however, that in respect of these conditions we fared better than did many other similar plants, and we are pleased to report the situation is now improving."

**To Remit Duties on Farm Tractors.**—One of the features of the Government programme for encouraging increased agricultural production for the benefit of Britain and her allies in the present war will be the remission of Customs duties on farm tractors imported for use on Canadian farms. Up to the present farm tractors coming from the United States have been subject to a duty of 17½ per cent., plus 7½ per cent. ad valorem under the War Tariff Act of 1915. Upon farm tractor engines up to the value of $1,400 these duties will be remitted as a war measure. These machines have proved of great use in drawing plows to break up the land.

**Big Production at Trail Refinery.**—The great metallurgical operation out at Trail, B.C., is again getting into its stride. The Consolidated Mining & Smelting Co., with fairly adequate labor, in the month of January produced metals in excess of a million dollars in value. The production included over 1,000 tons of high-grade zinc, over 500 tons of refined copper, over 1,600 tons of lead bullion, over 3,500 ounces of fine gold, and almost 100,000 ounces of silver. In addition, the usual quantities of sulphuric acid, hydrofluosilicic acid and copper sulphate were turned out. Over 38,000 tons of ore were treated.

**Railway Earnings Show a Decrease.**—The gross earnings of Canadian railways for the month of January, 1918, owing to the cold and stormy weather and the consequent hindering of traffic, showed a decrease from those for the corresponding month last year. Earnings of the three principal Canadian railways aggregated $17.368.662 this past January, a decrease of $82,326, or 5 per cent. The C.P.R.'s earnings last month were $10,570,000, an increase of $629,000; Grand Trunk's, $4.083,362, a decrease of $594,026; C.N.R.'s $2,715,300, a decrease of $117,300.

**Wish to Control Own Resources.**—Provincial control of the natural resources in Manitoba, Saskatchewan, Alberta and the railway belt in British Columbia will be one of the subjects discussed at the conference with provincial premiers at Ottawa next week. The old government was committed to this policy, and the new western ministers have been advocates of provincial control for some years. At present the three prairie provinces receive a cash subsidy in lieu of the public domain. As they wish to retain this subsidy as well as securing control of the lands, the other provinces are concerned.

**The Canadian Crocker-Wheeler Co.** of St. Catharines, Ont., whose fiscal year ended Dec. 31 last, reports a favorable condition of affairs in 1917 in comparison with the 1916 period. A new machine shop and power house were completed during the year and R. A. Stinson, the vice-president of the company, announces that the outlook for business in 1918 is most encouraging. They have recently completed the equipment and re-tooling of their ordnance department for the manufacture of 75 mm. French shells for the American Government. The contract for these shells will keep this department busy at least eight months.

**To Develop Canadian Fuel Resources.**—The Advisory Council for Scientific

and Industrial Research has forwarded a memorandum to the government, urging that immediate action be taken to make available the varied fuel resources within the Dominion for use in the coming year. At the request of the Institute of Civil Engineers of Great Britain, the council will also bring before the government and certain manufacturers the importance of Canada associating itself with the movement recently organized in Great Britain, the United States and France for combined action in connection with the standardization of various engineering products used and exported from these countries.

**War Mission to Act for Canada in U.S.** Canada has established a war mission at Washington. Lloyd Harris, who has been associated with the British War Mission there for several months, will act as chairman. The Canadian War Mission, it is announced, "will act in the closest conjunction with the British War Mission at Washington as well as with the British Embassy. "It will act on behalf of the various dpartments of the Canadian Government in respect of negotiations of purely Canadian affairs and will exercise general supervision and direction over all officers of the Government of Canada stationed in the United States in respect of matters connected with or incident to the prosecution of the war."

**Canada Copper Corporation.**—The Canada Copper Corporation is making rapid progress in its preparation to extract ore at a minimum cost. A main transportation tunnel, to be 2,900 feet long, was started in September, and is now two-thirds completed. Recent rate of progress exceeds 600 feet a month. On finishing the tunnel the company will immediately drive a large "raise" to connect with the upper tunnel and works, where preparations have been practically completed for mining the overlying ore body. The power line, which transmits a current generated at Bennington Falls, 100 miles distant, is ready for operation, and the C. P. R. has completed the preliminary work on the branch line to connect the mines with Princeton, B.C., where the mill is located. It is believed that these facilities will effect the highest degree of operating economy.

**Freighter Launched at Polson Iron Works.**—The cargo steamer "Asp" was launched at Polson Iron Works, Toronto, Monday afternoon. The "Asp" is a sister ship to the "Tento," which was launched last fall. Both vessels were built for Norwegian interests, but will be taken over by the British Government. Fears that the launching could not be carried out because of the thickness of the ice proved unfounded. Gangs of men cut away the ice barrier and at 3.20 the vessel slipped easily into the water without any mishap. Mrs. Winstrup, the wife of the captain who is superintending the construction of the vessel, performed the christening. The "Asp," like the "Tento," is 261 feet long, has a beam of 43 feet 6 inches, and depth of 23 feet. It will be fitted with triple expansion marine en-

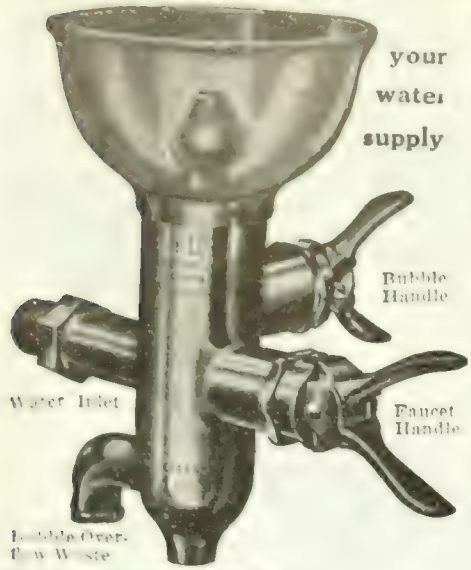
"PURO - FY"

(MADE IN CANADA)



THE American Museum of Safety conferred a Gold Medal Award upon the Puro Sanitary Drinking Fountain at the First International Exposition of Safety and Sanitation.

The Puro Sanitary Drinking Fountain won because it deserved to win. Puro had merits that made it stand head and shoulders above any other drinking apparatus.

**Safe Simple**
**SANITARY Economical**
**Quickly Attached**

These are the qualities that forced the leading safety and sanitary engineers to pick Puro in preference to all others.

No device can be as efficient that does not contain all these qualifications and Puro was not used for first place, Puro was first.

Don't be satisfied with half way goodness, or makeshift drinking arrangements for your employees.

If the men in your factory must drink, give them a clean drink.

Puro is [illegible] rust or corrode.

Puro is economical. It allows just the proper amount of [illegible] water to come through the bubbler. No spurting, no overflow, no loss. Puro regulates itself. You can [illegible] in five minutes.

Tell us how many men in your factory and your water pressure in pounds.

We'll tell you just what it will cost to "PURO-FY" YOUR WATER SUPPLY.

**Normac Machine Co.**

55 Vine Street, St. Catharines, Ont.

[illegible] and two boilers 14 by 12 feet. It is of 3,500 tons burden.

**The Canadian Car and Foundry Co., Montreal,** has recently received a contract from the French Government, through the New York office, for the construction of twelve mine sweepers. These vessels are to have an overall length of 143 feet and a beam of 22 feet 6 inches, and the approximate value of the construction order will be $2,500,000. The company has decided to erect a plant at Fort William, Ont., adjoining their present car works, where the conditions are very suitable for a shipbuilding plant of this description. The present depth of water at the existing dock and water front is about thirty-five feet, being amply sufficient to accomodate this particular type of vessel. Covered sheds together with the necessary crane runways and all other facilities will be constructed at once so that no delay will be experienced in meeting the terms of the contract. It is not thought that much additional machinery will be required, owing to the available equipment at the present car factory, which it is expected will be utilized for the mechanical operations in connection with the building of the vessels. The company will be relieved of the duty of obtaining the necessary steel for this work, as arrangements have been made whereby the U.S. Steel Co. will furnish the required material in ample time for the filling of the contract. It is anticipated that the twelve vessels will be completed before the closing of navigation in the fall of 1918 so that they can be brought down the Great Lakes to he ocean terminal under their own steam.

## TENDERS

**Hamilton, Ont.**—Tenders will be received by the Board of Control, up to Monday, March 4, 1918, for supplying the city with the following materials: Castings (ordinary and special), iron pipe, hydrants, valves, extension boxes, hardware, lead pipe, pig lead, road oil, lubricating oil, flux, fuel oil, lumber, gasoline, brass work, including ordinary and special brass castings for the Water Department. Specifications and form of tender for all of the above can be obtained at the office of the City Engineer, Hamilton, Ont.

**Melbourne, Australia.**—Tenders for the following may be addressed to the Director of Navy Contracts, Navy Office, Melbourne: Supply, delivery and erection at Garden Island, of one (1) 200 horsepower prime mover set of either semi-Diesel type or other heavy oil engine direct coupled to 2-65 K.W. 240 volt D.C. electric generating set. All accessories, tank and fittings to be supplied by tenders as per specification. Date of closing June 7, 1918. Tender forms are open for inspection at the Department of Trade and Commerce, Ottawa. File No. 20117.

**Ottawa, Ont.**—Tenders will be received until Friday, Feb. 22, for the purchase of the car ferry steamer Leonard, formerly engaged in transferring cars between Levis and Quebec. The Leonard was built in 1914, and designed to fulfill the requirements of the highest class in Lloyd's for a vessel of this type. Her principal dimensions are: Length over all, 313 feet; breadth, 65 feet; depth, 23 feet; draught, 16 feet. The Leonard is now lying at Levis, Que., below the dry-dock, where she can be examined. Information as to the steamer's engines, boilers, steam pressure, speed, bulkheads, tracks, gangways, ice breaking, etc., etc., etc., and further information can be obtained at the Department of Railways and Canals, Ottawa.

**Ottawa, Ont.**—Tenders will be received until March 18, 1918, for heating and ventilating equipment required in the reconstruction of the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all materials, tools, appliances, scaffolding, apparatus and labor required for the installation of the heating and ventilating equipment as called for in the plans and specifications. All information can be obtained at the office of the general contractors, P. Lyall & Sons Construction Co., Ottawa. A set of plans and specifications may be had by depositing an accepted bank cheque for twenty-five ($25.00) dollars made payable to the Honorable the Minister of Public Works, which will be returned if the intending bidder submits a regular bid.

**Ottawa, Ont.**—Tenders will be received until March 18, 1918, for rolled steel casements and bronze covered frames and sash for the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all material, tools, appliances, labor, etc., as required and described by the plans and specifications for (a) rolled steel casement; (b) bronze covered frames and sash. Separate tenders to be submitted for "a" and "b." The work included under this contract shall be commenced immediately on the signing of the same, or at such time as may be directed, and be carried out in such a manner as to insure the completion thereof by Sept. 30, 1918. Plans and specifications, and any other information required can be obtained at the office of the general contractors; P. Lyall & Sons Construction Co., Ottawa.

## CONTRACTS

**Toronto, Ont.**—The Jackson Lewis Co. have the general contract for two dry kilns, costing $10,000, for the Canadian Aeroplane Co.

**Winnipeg, Man.**—Thos. Kelly & Sons, Lindsay Bldg., have the general contract for reinforced concrete pipe line, etc., costing $482.626, for the Greater Winnipeg Water District, 501 Tribune Bldg.

**Montreal, Que.**—The Chilean Government has placed an order for twenty engines with the Montreal Locomotive Works, a subsidiary of the American Locomotive Works. The local company is now completing an order of twenty engines for the Union of South Africa.

# MARINE

**Victoria, B.C.**—The Wallace Shipyards have secured a contract for four steel steamers from the Dominion Government. The vessels will be 5,100 tons deadweight capacity.

**Vancouver, B.C.**—The Union steamer Cassiar has left for the North after her spring overhaul and refit, taking the place of the Cheakamus, which is in turn going on the ways.

**Vancouver, B.C.**—The Taylor Engineering Co. is designing and will start construction within 30 days of a full-powered wooden oil tanker for the International Petroleum Co. This new tanker, when completed, will serve the British Columbia coast trade.

**Port Arthur, Ont.**—J. F. Paige, general manager of the Port Arthur Shipbuilding Co., has officially announced that the company had received contracts for the construction of five canal size freighters and eight other boats. Mr. Paige stated that the freighters would be numbered 19, 20, 21, 29 and 30.

**Winnipeg, Man.**—It is reported that F. Hutchings, president of the Great West Saddlery Co. of this city, and one of the best-known financiers in Manitoba, is head of a syndicate that has secured a tentative contract to build twelve ships on the Pacific Coast. It is understood that the company is now negotiating with the federal authorities.

**Department of Marine and Fisheries.**—Public notice is given that the Minister of Marine and Fisheries, under the provisions of section 27 of the Canada Shipping Act, has granted permission to change the name of the tug "Dorthy Symons" of Vancouver, Official Number 126,542, owned by the Department of Public Works, to that of "Nakusp."

**Montreal, Que.**—A Canadian shipping syndicate has purchased control of the Ogdensburg Coal & Towing Co. Two corporations will be formed, one capitalized at $200,000 to continue the business here, and the other at $1,000,000 to operate at Montreal. W. L. McDougall, of Montreal, will be president and general manager of each. The company has arranged to supply fuel to the vessels of the Canada Steamship Lines plying on the St. Lawrence route.

**Victoria, B.C.**—It is announced at the offices of the Imperial Munitions Board that the War Yukon is in the hands of the engineers at the new assembling plant. The contractors, the Cameron Genoa Mills Shipbuilders, have, with the exception of stepping the masts and other deck work, which will be done by the utilization of more adequate hoisting facilities at the Ogden Point works, practically completed their part of the contract as far as the War Yukon is concerned. The main engines for the vessel have been lying at the assembly plant for several weeks past and immediately the new hull is safely moored alongside the government pier a start will be made in assembling her machinery.

# Recent Advances in Canadian Metallurgy*

By Alfred Stansfield, D.Sc., F.R.S.C. **

*The mineral resources of Canada have been [illegible] to the [illegible] being of vital importance. The developments [illegible] convincingly the variety and extent of the [illegible] facilities for production so brought about [illegible] present position of world-wide importance.*

IN writing of "recent" advances, it becomes necessary to decide on some definite period of time on which to report, and this surprising war has given such an impetus to Canadian metallurgy that it will be appropriate to regard the commencement of the war as the epoch from which to measure these advances.

### Metal Markets in War Time

The first effect of the war was to restrict the regular operation of metallurgical plants and to stop al lnew developments. This followed naturally from uncertainty in the financial situation and an immediate lack of money. Looking back at the situation it seems strange that markets should fall, and metal production decrease, when it must have been certain that nearly all the metals would be needed in increasing quantities for warlike operations. After about six months this demand became apparent, the prices of metals began to rise, and their production was consequently stimulated. An early development was caused by the shell committee's need of brass for cartridge cases. Copper for this purpose could be obtained without great difficulty, but zinc, of a suitable degree of purity, was very difficult to obtain even at a greatly enhanced price. Zinc ores had been mined in British Columbia for a number of years, but it had not been found practicable to smelt them in this country, and zinc ores, or concentrates, were shipped to smelters in the American zinc districts. After the outbreak of the war, the American smelters refused to accept ore shipments from Canada; a refusal which was considered by many as being caused by German control or interest in the smelters. Whatever was the cause the situation was clear: the shell committee needed zinc, and the British Columbia miners had the ore, while the American smelters were unwilling or unable to convert the one into the other.

### Zinc Production

Zinc differs from many metals in the fact that the smelting process yields a metal which is marketable without the need of any refining. The purity of the "spelter" depends mostly upon the character of the ore from which it is produced, thus "high-grade" spelter, from specially pure ores will contain less than 0.1 per cent. of total impurity, while "Prime Western" spelter, obtained from leady ores, may contain as much as 1.5 per cent. of lead. This difference in the purity of different brands of spelter is not objectionable, since the uses to which they are put vary greatly in requirements; prime Western spelter is amply good enough for galvanizing, while high-grade spelter is none too good for making brass for cartridge cases. The British Columbia zinc ores are in general mixed with ores of lead, and it would be impossible by the usual smelting process to obtain a spelter that would meet the requirements of the shell committee.

A process was under investigation, at that time, for obtaining zinc from these complex ores by roasting, extracting the zinc as sulphate by means of sulphuric acid and water, and separating metallic zinc from this solution by electrolysis, using insoluble anodes. This process was not new, but it had failed hitherto owing to technical difficulties in the leaching of the ore, the purification of the solution and the production by electrolysis of compact zinc that could be remelted. The cost, moreover, was too high to make it profitable in view of the low price of zinc before the war. A commission was appointed by the Minister of Militia to investigate the situation with respect to the supplies of copper and zinc. This commission concluded that the electrolytic process offered the greatest probability of filling the need, and made arrangements with the Consolidated Mining and Smelting Company, which led to the establishment at Trail of a plant for producing electrolytic zinc from the British Columbia ores. At the present time this plant has a capacity of about 300 tons of zinc per week.

Before the war the writer carried out an elaborate investigation for the Department of Mines on the electric smelting of zinc ores, but practical success was not reached. During the war this research has been taken up again for a mining company with more success, both in the laboratory and in a small plant at Shawinigan Falls. Commercial success has not yet been obtained, but it is expected that the work will be resumed during the present year. The writer has also been interested in the production of zinc oxide for paint by the Wetherill process; he helped to design and operate an experimental plant in Montreal, and following on from this, a full-sized plant has been erected at Notre Dame des Anges.

The metallurgy of zinc, as well as that of lead, copper and silver, has been materially improved during recent years by the application of the flotation process by means of which the zinc minerals can be separated more perfectly from the gangue, and in some cases from other metallic minerals.

### Copper Situation

The copper situation, investigated by the commission, was entirely different; copper ores are mined and smelted in British Columbia on an enormous scale for the production of copper matte, and in some cases the matte is bessemerized for the production of metallic copper. Crude copper, however, is of no use until it has been refined, and all the copper derived from British Columbia was sent to the United States as ore, matte, or blister copper, in order to be refined in the American refineries.

The problem before the commission was the establishment in Canada of an electrolytic refinery, so that Canadian copper could be made available for Canadian needs of that metal. The problem was complicated by American interests in the Canadian copper smelters, by contracts with American smelters and refiners, by heavy freight charges between British Columbia and the points at which the copper would be used, and by the lack in Canada of rolling mills and other works for turning the refined copper into sheets, rods, wires and other forms required by the Canadian market. Although the price of copper rose to a very high figure, the shell committee was able to obtain supplies of pure copper from the States, and there was not sufficient urgency to justify the Government in establishing a copper refinery in British Columbia in face of the natural obstacles already mentioned.

In the meantime the Consolidated Mining and Smelting Company established at Trail a small refinery, which is now in operation, and has an output of about 10 tons per day, and the copper and zinc from Trail have both been used in the Dominion Copper Products' plant in Montreal for making brass for the manufacture of cartridge cases. It must not be supposed that the erection of this small refinery solves the general problem outlined above, although it may serve by way of example to help in settling it at some later date. The copper furnaces at Trail smelt ores of gold and silver as well as ores of copper, and the resulting crude copper is so rich in the precious metals that the company finds it more satisfactory to refine the metal at Trail, thus securing the gold and silver contents, instead of shipping the crude metal to distant refineries which would entail very serious difficulties in

*Read before the Canadian Society of Civil Engineers at Montreal, Feb. 14, 1918.

**Birks Professor of Metallurgy, McGill University.

British Columbia amounted in 1913 to about 23,000 tons, or about 60 tons per day, so that a practically unanimous co-operation of all the producing companies would be needed to support a single re- [illegible] of time, a large refinery will be operated in British Columbia for the treatment of Western ores, but this will depend on the erection in that province of mills for working up the refined copper, and of the growth of a market in Western Canada that will absorb a large part [illegible]

The production of copper in British Columbia has increased steadily during [illegible] years as the following figures show, this increase being largely due to the development of the Granby Company's smelter at Anyox. Recently the copper smelter at Ladysmith has changed hands and has again been put into operation. This increase of copper production will tend towards the establishment of a large refinery on the coast. The introduction of the flotation process has modified copper metallurgy in recent years. Low grade ores, which were at one time smelted in blast furnaces, or even treated by wet (chemical) methods, are now crushed and ground to a fine powder and concentrated by flotation. The flotation concentrate, on account of its powdery condition, can be treated most easily by roasting in mechanical furnaces and smelting in reverberatory furnaces.

PRODUCTION OF COPPER IN BRITISH COLUMBIA IN TONS

| [illegible] | 1914 | 1915 | 1916 |
|---|---|---|---|
| [illegible] | [illegible] | 28,000 | 32,000 |

Outside of British Columbia, the largest production of Canadian copper is from the Sudbury district, where it occurs in association with nickel. The production in Ontario, nearly all being from the Sudbury district, is about half the production in British Columbia, but its separation and refining is dependent on the separation of the nickel and copper, and can only be considered as a by-product from the extraction of nickel.

### Nickel Production and Refining

At the beginning of the war, two companies,—the International Nickel Company and the Mond Nickel Company,—were operating in the Sudbury district. These companies smelted the ore to a matte containing from 20 per cent. to 30 per cent. of nickel and copper, and [illegible] of about 80 per cent. of nickel and copper, containing little else than sul- [illegible] in proportions depending on the relation between these metals in the original ore. The Mond Company shipped their matte to England for treatment by the Mond [illegible] South Wales, while the International Company treated their matte by the "salt cake" process at their refinery at Constable Hook in New Jersey.

It has for a long time been regarded as an economic injustice to Canada that the copper-nickel matte should be sent to the States for refining, but it was maintained by the company officials that the cost of refining it in Canada would be very much higher than in New Jersey. After the outbreak of the war, attention was repeatedly called to the situation, because it was feared that the nickel passed into German hands, and as a result of this outcry the International Company agreed to erect in Canada a refinery sufficiently large for the British requirements of nickel. This refinery is now being built at Port Colborne, in Ontario, and should be in operation early in the present year; it will have an initial output of 7,500 tons of nickel per annum. In the meantime a new company has entered the field.

The British America Nickel Corporation, a strong British-Canadian company, which is controlled by the Imperial Government, has acquired about 17,000 acres of mineral land in the Sudbury district, and early in 1917 began the construction of a large smelting and refining works at the Murray mine. This company will smelt the ore to matte, and bessemerize the matte on substantially the same lines as the older companies; but the production of refined nickel and copper from the matte will be carried out by the Hybinette electrolytic process, which is now in operation in Norway. The new plant is expected to be in operation in 1919, and will have an output of 6,000 tons of refined nickel per annum. In 1913, the last whole year before the war, nickel matte, containing 25,000 tons of nickel was sent abroad to be refined; during 1917 the output was about 42,000 tons, and by 1919 we may expect a production of some 13,000 tons of nickel in Canada in addition to perhaps three times this amount in matte refined abroad.

During the year 1914 one million tons of nickel-copper ore was mined and smelted in the Sudbury district, and the resulting matte contained 22,700 tons of nickel and 14,000 tons of copper. Some 400,000 tons of iron, equal to half the Canadian production of pig iron, was slagged in the furnaces and thrown over the dumps, and 300,000 tons of sulphur was discharged into the atmosphere. This sulphur would produce one million tons of sulphuric acid, which is equal to one-fourth of the consumption of the United States, but it is not considered worth while to save this at the present time on account of the cost of transportation of the acid to points at which it could be used. Projects have been considered, however, for saving the sulphur in the elemental state so that it could be shipped easily, or for collecting the $SO_2$ gas in the liquid state and using it for the manufacture of wood pulp. With regard to the waste of iron, it may be remembered that more than half the nickel produced is used in the manufacture of nickel steel, and with respect to this part of the output, there is therefore no need to separate from the nickel the iron which was originally associated with it.

Attempts to make a nickel pig-iron which could be converted directly into nickel steel were met in the past by the difficulty that the copper, which is almost always present in the ore, was supposed to be harmful in the steel. During recent years, however, it has been found that if the copper is present in moderate amounts, not more than one third of the nickel contents, a nickel-copper steel is entirely satisfactory and may be expected to replace the usual nickel steel for many purposes. Many tons of this steel have recently been made from the Sudbury ore, by the process devised by Mr. Colvocoresses; and its mechanical properties and suitability for many purposes will soon be ascertained. It should be possible to employ this process on a large scale, although, of course, it is limited to ores with a small content of copper. Care will be taken, by suitable admixture of the ores and otherwise, to maintain a uniform product, and it may be added that the small amount of precious metals contained in the ore cannot be saved if this process is used.

In connection with the advances in the nickel industry, mention must be made of the investigation of the Ontario Nickel Commission, which was appointed in 1915 and brought out its report in 1917. This commission has investigated the ores, smelting processes, refining methods, properties and uses of nickel, not only in Canada, but in all parts of the world where nickel ores are mined. They have considered the subject from many points of view, and have produced a very valuable report. Geo. T. Holloway, the metallurgist of the commission, died soon after the completion of his work.

The production of iron and steel in Canada fell off considerably at the beginning of the war, but revived later, and at the present time, owing to the large demands for the manufacture of munitions, is larger than ever. This will be seen from the following table:—

PRODUCTION OF IRON AND STEEL IN SHORT TONS*

| | 1912 | 1913 | 1914 | 1915 | 1916 | 1917 |
|---|---|---|---|---|---|---|
| Canadian iron ore | 216,000 | 307,000 | 245,000 | 398,000 | 340,000 | 190,000 |
| Pig iron | 1,011,000 | 1,129,000 | 783,000 | 914,000 | 1,169,000 | 1,187,000 |
| Steel ingots and castings | 957,000 | 1,169,000 | 828,000 | 1,020,000 | 1,454,000 | 1,735,000 |
| Electric furnace steel | | | 61 | 5,600 | 13,000 | 50,000 |

### Electric Iron Smelting

The production of steel has advanced faster than the production of pig-iron, the latter being restricted by the need of importing the ore, and in some cases

*The figures for production in this paper have been taken from the reports by John McLeish, who kindly furnished the writer with approximate data for 1917. The amounts, in most cases, have been stated in even thousands, as in this form they are far more easily read and compared.

even the fuel, for smelting in Canadian furnaces. The amount of ore mined in Canada is but a small proportion of the amount smelted, but if we include Newfoundland ore, as we reasonably may, we would find that rather more than half the iron is derived from Canadian ore.

Just before the war the writer visited Sweden in order to study the electric iron smelting industry in that country, and made a report to the Mines Branch in the fall of 1914. At that time it did not appear that electric iron smelting could be undertaken profitably in this country, but in the year 1916 he made a fresh study of the situation in connection with a report by Mr. John Dresser on "Part of the District of Lake St. John, Quebec," and came to the conclusion that there is hope for electric pig-iron in Canada. In considering the possibility of smelting electrically the titaniferous magnetites of that district, it appeared that although pig-iron produced in that way could never compete, as regards price, with the product of the blast-furnace using coke as fuel, still it should be possible to make a limited production of high class white pig-iron which would command a high price and thus sell at a profit. Besides producing a very desirable quality of pig-iron, and incidentally helping the steel makers, this would have the advantage of utilizing ores which are at present worthless, and of employing water-power which now runs to waste.

### Electric Furnace Steel

Although electric smelting of iron ores is still in the future, the electric furnace has been employed very largely for making steel, as is shown in the table. The electric furnace has not been used in this country to any extent for making new steel, but mostly for remelting steel scrap into shell billets. For this purpose several furnaces are in operation in Montreal and district, and at Toronto a large plant, containing ten 6-ton furnaces has been built by the Munitions Board for remelting shell turnings and other scrap. During the period under consideration the Armstrong Whitworth Company have built up an electric melting plant for the production of all kinds of tool steel in their works at Longueuil. The electric steel plant at Belleville has made a quantity of very good steel from titaniferous iron ore, but at that time it was found cheaper to employ steel scrap than to smelt ore. The plant has recently been fully occupied with the production of ferro molybdenum for the British Government.

### Ferro Alloys

There has been, for a number of years, a moderate production of ferro-alloys in Canada amounting in 1913 to 8,000 tons, in 1914 to 7,500 tons, and in 1915 to 10,800 tons. This production consisted mostly of ferro-silicon made in electric furnaces at Welland by the Electro-Metals Limited, and in 1915 a little ferro-phosphorus made at Buckingham, P.Q., by the Electric Reduction Company. In 1916 the production had risen to 28,600 tons, valued at $1,777,000, and included, besides ferro-silicon and ferro-phosphorus, a considerable production of the valuable product, ferro-molybdenum, which is now made in electric furnaces at Belleville and Orillia. Ferro-silicon is now made at Shawinigan as well as at Welland. For the manufacture of steel there is a considerable demand for ferro-manganese and spiegel-eisen, and experiments are now in progress for making these alloys from Canadian manganese ores. The production of ferro-chrome is also under consideration.

### Gold and Silver

More than 80 per cent. of Canadian silver comes from the Cobalt region, and, during the period of the war the production has ben falling slowly as the mines became exhausted, and on account of the scarcity of labor and supplies. The recent rise in price of silver has, however, stimulated the production. The metallurgical treatment of the ores had been worked out prior to the war, but the development of the flotation process has improved the concentration processes at Cobalt. The production of silver in 1916 was 25,600,000 ounces, valued at $16,800,000, and in 1917 was about 23,500,000 ounces. The production of gold in Canada was varied from about 800,000 ounces to 1,000,000 ounces per annum during this period; gold is obtained from Yukon, British Columbia and Ontario. Before the war the two Western provinces had the largest outputs, but since the growth of the Porcupine district the production of Ontario is nearly equal to the sum of the other two, and the total production has somewhat increased.

### Lead

The need of lead for bullets caused an increase in the mining and smelting of lead ores, with the result that in 1917, when this demand was reduced, there arose a difficulty in disposing of the lead already on hand and undergoing treatment. The management of the Trail Smelter informed the miners that they would only take ores that were relatively free from zinc, so as to reduce the ore supply, and at the same time obtain a better grade of ore. This ruling gave rise to a great outcry, and arrangements were made with the Munitions Board to take a larger amount of the metal.

The success of the Victory Loan should enable the production to be taken up by the Board, but it may be pointed out that the normal Canadian market for lead and lead products is amply sufficient for the Canadian production, and it is only necessary to arrange for the lead being converted into marketable forms. Some advance has been made in this direction, and there are two "corroding" plants in Montreal for the production of white lead, but red lead and litharge should also be manufactured. The usual production of lead is about 20,000 tons per annum, but in 1917 it amounted to 28,000 tons. The Cottrell electrical precipitation process for the collection of smoke and fume has proved of great service in the treatment of ores of lead and zinc, and has been introduced at the Trail smelter.

### Antimony

The metal antimony was selling at about 8 cents per pound, but early in the war its price rose to 16 cents, and later to more than 40 cents a pound. Antimony is used to a large extent alloyed with lead for making shrapnel bullets, and supply was for a time insufficient for the need, so that bullets have been made of lead encased in a steel shell, the whole being arranged to have the same size and weight as the bullets of alloy previously in use.

Antimony is not produced to any extent in Canada although a small amount is derived from the electrolytic refining of lead at Trail. In view of the high price and unusual demand for the metal a mine of low grade ore at Lake George, New Brunswick, was reopened and after much patient work an efficient process was devised for extracting the metal from the ore by volatilization. An account of this process was recently presented to the Society by Mr. J. A. deCew. By the time that the process had been brought to a satisfactory condition, other suplies of antimony became available, the price fell, and the mine and smelter had to be closed.

The metal aluminum is made at Shawinigan Falls from bauxite which is imported from France and elsewhere as no ores of commercial value have been found in Canada. Figures for the production of this metal are not published as only one firm is engaged in the industry, but there is no doubt that the production has increased materially during the war, aluminum being needed in large amounts for the construction of aeroplanes and other military equipment. The value of metal exported from Canada in 1913 was $1,700,000; in 1914, $2,300,000; in 1915, $3,300,000, and in 1916, $5,200,000.

### Aluminum and Magnesium

The process of extracting aluminum from alumina (purified bauxite) consists, as is well known, in electrolysing fused salts to which alumina is added. Before the war this was the only operation in use in Canada, that depended on the electrolysis of fused salts, but a fresh industry of this kind has been now started—the production of the metal magnesium. Before the war this metal was made in Germany from the natural deposits of carnallite, but the war stopped this source of supply.

The writer succeeded in producing magnesium in the laboratory, and the process was developed into commercial operation at Shawinigan Falls. At present the crude materials are imported, but ultimately it is intended to use Canadian magnesite as the ore of this metal. Magnesium is now made in considerable quantities at this plant; it is used in the form of powder for star shells and

### Brass Melting and Rolling

In connection with the production of zinc and the refining of copper in Canada [illegible] and other metals into marketable forms. The Dominion Copper Products plant at Lachine has been built during the war for melting and rolling brass and copper for use in shell and cartridge cases. As the need for such products decreases, it is expected that this plant and Brown's Copper and Brass Rolling Mills in Toronto will be employed on a large scale for making brass and other non-ferrous alloys and for rolling these and the metals copper and zinc into forms suitable for use by Canadian manufacturing industries, so that a market will be found in Canada for Canadian copper, zinc, nickel, lead and other metals.

### INCREASED VOCATIONAL EQUIPMENT AT MONTREAL TECHNICAL SCHOOL

THE Military Hospitals Commission announces that, through the courtesy of the directors of the Montreal Technical School, additional space has been allotted in their spacious and beautiful building on Church Street for the installation of wood-working machinery as an adjunct to the carpenter shops. There are now being installed bandsaws, turning lathes, drills, etc., all to be operated by electric power. Since the inception of the vocational work, the directors have placed every facility of the school at the disposal of the department, now occupying ten class rooms and a motor garage.

Through the courtesy of the United Machinery Company there has also been installed an eighteen-foot Goodyear shoe-repairing outfit. This is a most necessary and desirable acquisition to the shoe-repairing classes. It is under the direction of an instructor secured from the London Trades Guild, of London, England, who has had a wide experience with some of the best London and Canadian shoe manufacturers.

### EXPORTS OF MANUFACTURES

[illegible] manufactured goods were valued at $33,635,790 in December, [illegible] standards, but very low figures on the [illegible] of the past year.

It was the smallest total to be entered in any Canadian trade return since October, 1916. It was $21,000,000 less than the total for December, 1916, and $55,000,000 less than in November, 1917. It compared with the record-breaking figues of $104,000,000 reported in the return for July last. Concurrently Canadian imports were the smallest reported for any month last year.

As noted in connection with the complementary figures furnished by the American trade returns, the decline is to be viewed as one sequel to the United States' embargo on exports of raw materials—an embargo which has been felt with increasing force since the end of last summer.

Growth in Canada's manufactured exports will depend next year very largely on the extent to which the embargo can be modified in favor of Canada. Hence the importance attached to the recent move to secure a War Trade Board, which could act officially for all Canadian manufacturers in negotiations at Washington that must now be carried on by the manufacturers individually.

### PEAT AND LIGNITE AS FUEL

PRODUCTION of lignite and peat as a means of coping with the fuel situation next year is being investigated by the cabinet committee on reconstruction and development, of which the Hon. A. K. MacLean is chairman. A conference on the question was held at Ottawa on Feb. 5, when Deputy Fuel Controller Peterson, Dr. McCallum, head of the council on scientific and industrial research, and R. A. Ross, chairman of the fuel committee of the research council, spoke of the value of lignite in bricks as a substitute for anthracite. Dr. Hanel, of the mines department, told of the available peat areas. There will be further meetings, and every effort will be made in the coming season, not only to increase the production of the coal mines, but, if possible, to develop the peat and lignite deposits in marketable form. Particular encouragement will be given to the production of wood for fuel.

### AUSTRALIAN MERCANTILE FLEET

THAT government ownership of steamship service has proved a great success in Australia is indicated in a report received here from D. H. Ross, Canadian Trade Commissioner at Melbourne. Mr. Ross states that the fleet of 15 cargo ships purchased in June, 1916, by the commonwealth government, has been actively employed at such remunerative rates that it is now estimated the net earnings have paid off the original outlay of approximately $10,000,000.

The fleet comprises 65,245 tons gross and 41,868 tons net register. In addition, the government shipping department has controlled since the beginning of the war 21 steamers and five sailing vessels. On delivery of the steamers and auxiliary vessels now under construction in the United States the government will be operating a fleet of 56 vessels. This fleet, Mr. Ross says, will serve a most necessary purpose in the transfer of Australian produce overseas, earning profitable returns on return voyages.

### EXPANSION OF MINERAL INDUSTRY ESSENTIAL

CANADA pays out more money for imported mineral products than she receives from her mines. The value of the mineral production for the calendar years 1913, 1914 and 1915 was $145,600,000, $128,865,000 and $137,100,000 respectively. The imports of products of the mine and manufactures of mine products for the same years were valued at $259,300,000, $181,676,000 and $146,324,000. As the imports also include manufactured, or partly manufactured products, they are much more valuable than the minerals we produce. If, however, Canadian minerals were turned into manufactured products in Canada, the present trade balance in minerals would be reversed.

It is only fair, though, to point out that Canada is under serious disadvantages in the matter of manufacturing. The relatively small and scattered population makes distribution from points of production to points of consumption both difficult and costly. Similarly, where, for example, coal is essential for reducing ore and for manufacturing, the cost of transportation necessary to bring the two raw products together bears heavily on manufacture. Copper, zinc and lead are produced principally in Western Canada, while the manufacturers and chief markets are in Eastern Canada.

In spite of these handicaps, a comparison of the figures for imports and those for production shows the opportunity that exists for developing a home market that will increase as the war goes on. Premier Lloyd George in his recent address stated that "Economic conditions at the end of the war will be in the highest degree difficult. There must follow a world shortage of raw materials, which will increase the longer the war lasts, and it is inevitable that those countries which have control of raw materials will desire to help themselves and their friends first."

The mineral resources of Canada, if developed, could supply not only our own needs but also permit the exportation of a surplus to other parts of the British Empire. There is, in Canada, an urgent need for production to pay for our war debt and borrowings before the war, and if we are to get the greatest value out of our mineral industry it is necessary that our metals and minerals be refined and made into manufactured or partly manufactured products in Canada. The production of certain mineral products in Canada has been stimulated by the war and new industries created. In the period of reconstruction, after the war, it will be necessary to safeguard and provide for the further extension of these industries.—*Conservation.*

# Some General Applications of Electric Welding Process*

Special Correspondence

*It is not some years since the first use of the various processes of welding iron and steel electrically, although their extended application has been comparatively recent. Much work impossible of accomplishment by other means can be done rapidly and economically by this method, the instances illustrated being of such as are unquestionably suitable.*

THE electric arc welding process is attaining an ever-widening field of usefulness in practically all branches of industry in which iron or steel are involved in any considerable quantity, and which thus afford opportunities for its application to many purposes incident to manufacture, repair and maintenance.

Although the several processes of welding iron and steel by means of the electric arc have been known for years, their application to useful service in the various industries has been comparatively recent. But since the necessary apparatus has been greatly simplified compared to what it was a few years ago and standard machines and switchboard equipment have been developed and introduced, the process is growing in favor and being generally adopted. In every case its application is favored by reasons of economy and efficiency and often because by means of it work may be accomplished which would be impossible for any blacksmith to do.

Perhaps its chief field of application is in plants such as iron and steel foundries, steel mills, railways, both steam and electric, general repair shops, shipyards, and marine repair shops as well as in general manufacturing work. A few typical instances of the nature of the work to which electric arc welding is put in several of the above classes of service may prove of interest.

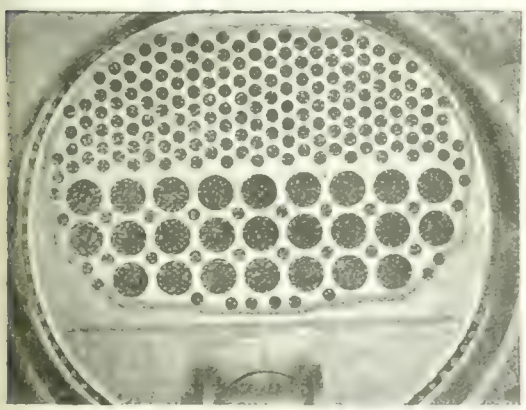

FIG. VIEW OF PATCHED TUBE SHEET IN LOCOMOTIVE BOILER

### Steel Mills and Foundries

One of the most serious mishaps to blast furnaces is to have the tap holes clogged with frozen metal. This necessitates shutting down the furnace and immense loss finally if the trouble is not immediately remedied. A heavy carbon arc provides a prompt and efficient means for overcoming the trouble. Such an arc, using 800 amperes or more, will clear out tap holes or tuyeres at the rate of about 3 feet per hour.

In steel foundries where heavy castings are made the question of cutting off the large risers becomes of considerable importance. This work is quickly and cheaply performed by the electric arc using the carbon electrodes with current as heavy as can be economically obtained. Many large castings are found to be slightly defective, due to misplaced cores, blow holes and cracks. The electric arc provides a means of reclaiming these castings speedily and with low cost by building on metal where needed, such as pads and lugs, also burning out and filling any cracks and holes in the castings. Scrap metal is economically cut by the electric arc into sizes suitable for the cupola.

Rolling mills have found that the electric arc provides a means for saving worn machinery and parts such as shafts, frames, cracked spindles, ladles, rolls with worn wobblers and other parts of rolling mill machinery. These types of equipment involve considerable expenditure if replaced and in many cases the expensive part is not damaged. For example a roll may have its wobblers as good as new. These repairs are easily made at a cost of less than 15 per cent. of the cost of a new roll. In Fig. 1 is shown a repair job of this nature which was accomplished by means of electric arc welding.

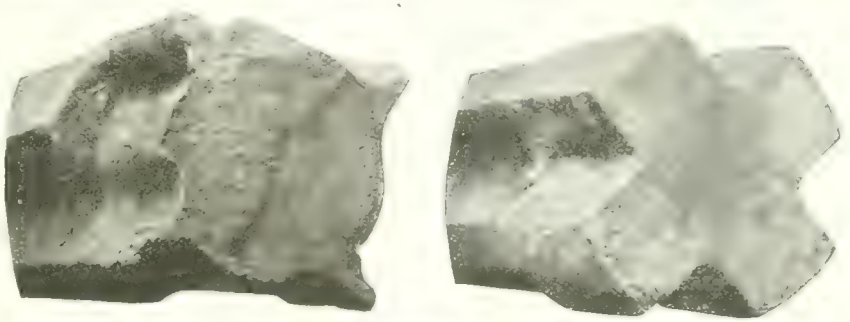

FIG. 1 WORN ROLLING MILL WOBBLERS REPAIRED BY ELECTRIC WELDING

### Railway Shops

In equipments used by railroads, both steam and electric, the construction is such that many of the repair operations are well suited for welding by the electric arc. On steam locomotives, for instance, there are a great many wearing parts which can be easily and cheaply made as good as new by the building up process. Worn spots on the wheels are built up in this manner, saving considerable time and money in the actual repair as well as additional saving due to the fact that the diameter of the wheel is not reduced. Worn mud rings can also be built up by welding on new material.

FIG. REPAIRING HULL OF STEEL SHIP SHOWING SCOPE OF APPLICATION

are constructed almost entirely of steel, repairs may be made to practically any

means of an arc welding set.

In a number of large ports, barges, which have been provided with arc welding equipments, are

and by means of cable led through port holes repairs may be made to the boilers or in any part of the ship.

The saving by this method consists partly in the fact that the ship need not be docked and partly in that the repairs can be effected without removing the defective part. Broken stern frames, propellers and damaged plates in the hull can be repaired quickly, although it is generally necessary to dry dock the vessel for repairs of this nature. The view of the damaged ship shown in Fig. 3 will afford some idea of the scope of the work it is possible to do with the electric arc.

### Miscellaneous Repair Work

One cause of considerable loss in manufacturing establishments is caused by taps or tap bolts breaking off in

either scrapping the casting or cutting out the tap with the gas flame and later building up again, redrilling and retapping. By means of the electric arc the metal is built on to the tap and brought up to the level of the casting and there welded fast to a nut. After

the tap or bolt removed without damaging the threads already cut. See Fig. 4.

Smoke stacks, ventilating flues, and similar structures are built and repaired economically by the electric process. The arc can be used for cutting the metal to the required size and later to weld it to the desired shape. Complicated joints are made without particular difficulty.

Cutting points of high speed steel are welded on to less expensive shanks of soft steel by this method.

Large parts of machine tools of various kinds are often broken and considerable expense and loss of time is involved if the ordinary methods of repair are followed or if

depended upon. The electric arc, however, provides means for repairing such parts at a minimum expense of time and cost. Fig. 5 shows a cast iron punch gear which has been successfully repaired by the arc weld without being removed from the machine.

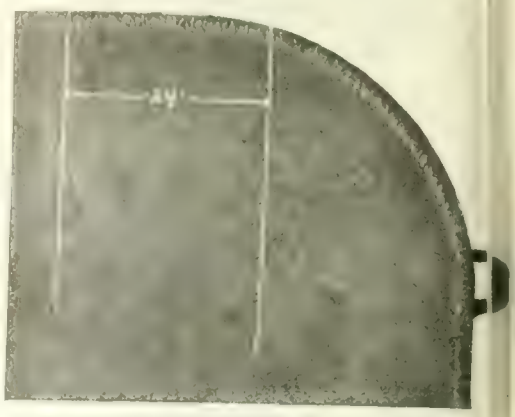

FIG. 6. TANK BOTTOM WELDED WITH METALL ELECTRODE ARC.

### General Manufacturing

The electric arc welding process is just as desirable in a manufacturing plant as it is in repair work. These

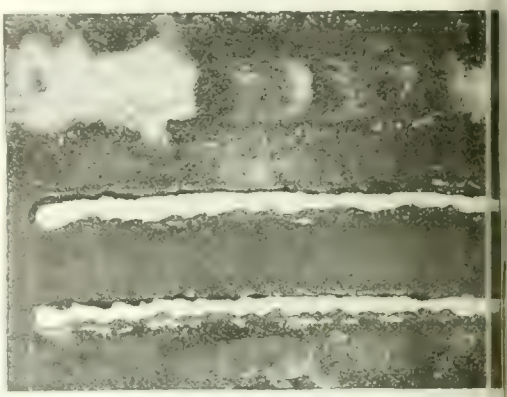

FIG. 7. ILLUSTRATING THE JOINING OF PLATE AND SHOWING THE APPEARANCE OF CUTS MADE BY ARC

equipments are used in automobile plants, manufacturing plants, locomotive shops, tank shops and plants of practically any description where metal is to

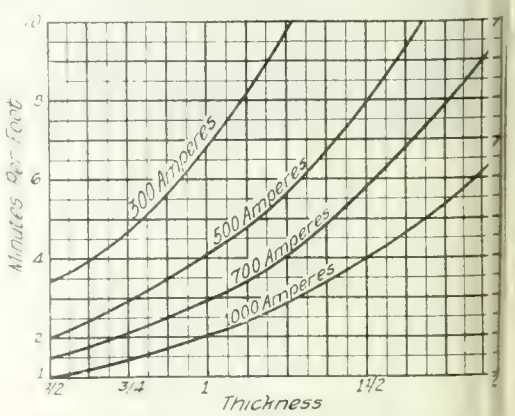

FIG. 8. TABLE OF APPROXIMATE CUTTING SPEEDS FOR DIFFERENT CONDITIONS.

be joined. A good illustration of this class of work is Fig. 6., showing the bottom of a tank welded by means of

the metallic electrode arc. Fig. 7 shows the weld made in joining two plates of steel by the carbon electrode process, also the appearance of cuts made by the carbon electrode.

Where cutting is to be done by the carbon arc the current used will depend on the cutting speed required. For light metal and where speed is not important 300 amperes is sufficient, but where the metal is 2 in. thick or more it is desirable to use heavier currents and up to 1,000 amperes can be used. Curves are shown in Fig. 8 giving the approximate cutting speed for different sections of metal and using different values of current.

## THE FRENCH STEEL INDUSTRY

BEFORE the war, France was already considered by experts as the richest country of the world in iron ore, after the United States. Besides the basins of Lorraine, which produce 3,000,000,000 tons of ore, she possesses the basin of Normandy, which, in an area of 40,000 square kilometers, contains, according to a recent estimate, nearly a billion tons of a superior quality of ore yielding 50 per cent. of iron. In 1914 21 grants in mining districts producing 1,152,000 tons a year, already existed in the departments of the Orne, Manche and Calvados, which yielded 648,000 tons with six grants only under exploitation. About the middle of 1916, a large society, entirely French, the Societe Normande de Metallurgie, was founded, with a capital of 40,000,000 francs, by Messrs, Schneider & Co., the great Creusot manufacturers, the Societe des Acieries de la Marine et Homecourt, and several shareholders belonging to the metallurgic world. This new society leased the foundries and fittings previously organized, or provided for, by the Societe des Hauts-Fourneaux de Caen, formed in 1892, and in July, 1916, started the works afresh now situated at Mondeville-Colombelle near Caen. About 30 kilometers distant is the Soumont mine, capable of yielding even now 4,000 tons of iron ore a month, and which, in the near future will have a larger output. The establishments of the Societe Normande de Metallurgie comprise gas and coke furnaces, large steel works, a flattening mill, smelting works and blast furnaces. Three stations and a railway line 33 kilometers long facilitate the transport service. The line was made by a branch society and runs between the above foundries and the Soumont mines. At present there are four batteries of 42 furnaces each, producing 1,000 tons of coke a day. In January, 1918, two other batteries, now under construction, will be in working order, and will bring the output up to 1,500 tons a day or 500,000 tons a year. The coke, collected by an ingenious system of inclined planes and chains, after being sorted out, is sent in trucks to government metal works. Gas undergoes a series of processes for the purpose of extracting the secondary products obtained by the distillation of coal such as tar, phenol, benzine, tuluol, naphthalin, sulphate of ammonia, used in the manufacture of explosives and for dyeing purposes, and which, prior to the war, were almost exclusively produced by interests in Germany.

The blast furnaces, the first of which has been recently inaugurated, are in themselves 29 meters high, but with their basements tower 45 meters above the foundry ground plot. They can produce 400 tons a day, which is said to be the largest output obtained in Europe up to the present day. To each furnace is affixed a battery of five metal cylinders, or "Cowpers," seven meters in diameter, for heating the air for the combustion of coke, and the reaction of carbon on the oxides of the ore, which is the source of production for cast iron. Three of these gigantic blast furnaces will be ready in the autumn of 1918 and the whole installation, when completed, will allow of an output of 450,000 tons of cast iron a year. The steel works, properly so-called, contain four converters of 30 tons, and five Martin furnaces of 30 tons, allowing of an output of 275,00 tons of Thomas steel and 125,000 tons of Martin steel every year.

The flattening mill can pass 500,000 tons of ingots a year, and is supplied with several reversible trains for the production of all small samples. The Societe already possesses stocks of iron ore sufficient to insure the supplies for its factories without any difficulty. It has had a large water tower, 66 meters in height, built in the neighborhood, with two reservoirs and a canal to the Orne, so that 10,000 cubic meters of water could be supplied hourly. A vast hall 200 meters long contains the electric machinery for distributing motive force, two turbo alternating generators of 3,000 kilowatts, one of 5,000, six gas alternating generators of 6,000 horsepower, and three of 3,000 horsepower. A private harbor has been built on the Orne canal, and it is now ready for vessels of 2,000 tons, and will soon be open to boats of 8,000 tons capacity.

The preceding facts show how the Societe Normande has been able to create in the midst of war one of the most important metallurgic centers in the whole of France. The mining industry of the entire region has followed its example. At present 30 fresh grants have been made for exploiting of the layers of iron in Normandy, Brittany and Anjou. On the other hand, the French government is preparing to work the Littry coal fields, situated between Saint-Lo and Bayeux. Lastly, owing to many recent improvements, trade with Caen harbor is increasing every day.

*From the Paris Chamber of Commerce bulletin.

## SALVAGE OF GREASE AND OILS FROM BRITISH MOTOR VEHICLES

THE grease removed in the cleaning of wheels, axles, and other parts of motor omnibuses, trucks, and other motor vehicles, is now utilized by the London General Omnibus Co., London, England. The process of reclaiming the oil is thus described in the *Commercial Motor*.

Before the war kerosene was largely employed for the cleansing of engines and other parts of vehicles, but now its consumption is restricted to the barest minimum, the net effect being the saving of five-sixths of the former consumption. Kerosene, as a matter of fact, is now only employed on certain parts of the mechanism for the cleaning of which there is no practical substitute. For the cleaning of wheels, axle casings, and front axles, a weak solution of hot caustic soda is employed.

When engines, gear boxes, back axles, or any other parts are stripped for overhaul, a very great saving is effected over former practice.

### Process of Reclaiming

The unit is dismantled and the parts are placed in a cradle and dumped into a tank of water into which a jet of steam is turned so as to bring the water to boiling point. Caustic soda is added to the water until a solution of about 3 per cent. strength is obtained. The whole of the grease is removed from the parts in the process of boiling and comes to the top of the water. Before the contents are removed the grease is drawn off the top. This is done through an overflow pipe which leads into a barrel.

The cradle of parts is then transferred to a second tank of clean, boiling water, which finishes the cleansing and, as the parts are drawn out quite hot, they drain perfectly dry and absolutely clean.

The result, so far as cleanliness of parts is concerned, is considerably better than if kerosene had been used. All minute parts of metal, dirt, and grit go to the bottom of the first cleansing tank.

### Oil Put Through Process

The London General Omnibus Co. has a central depot for reclaiming oil and washing rags, and to this depot the barrels of waste oil, as they are obtained from the various garages, and the rags are sent.

At this depot there is a battery of three tanks erected over a furnace, each of which is filled to about two-thirds with water, which is brought up to the boiling point. The barrels of oil as they come in are drawn off into the first boiling tank, a little being added at a time. The oil is thoroughly boiled, and when it overflows into the second tank (by the adding of more oil to the first) it has become almost fit for use again, but it passes into the second tank and is given a second boiling, and then on to the third tank, where it goes through its final stage of cleansing, and from the last tank it is drawn off and run into barrels.

### Salvage of Rags

As to rags, their price to-day is much higher than before the war, when they were thrown away after being used. At present every rag is collected in each garage and sent once a week to the central cleaning depot.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

## MACHINING A GAS ENGINE CYLINDER

By C. [illegible]

THE cylinder shown in Fig. 1 was used on a 1½ horsepower gas engine, the cooling of the form type and [illegible] and as large quantities [illegible] it was necessary that the methods of

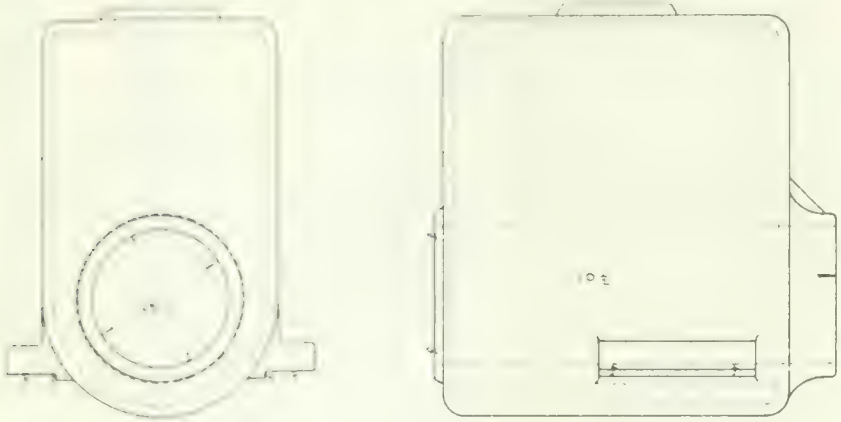

FIG. 1.

manufacture would enable the engine to be placed on the market at the lowest possible cost as it is necessary to compete with many of the cheaper makes of engines then turned out. The bore of the cylinder was 3½ in. while the length of the cylinder casting was about 10½ in. The water jacket extended entirely around the working barrel but did not run through into the cylinder head as this was air cooled. At the one end the barrel also extended for a short distance from the jacket, forming a very convenient means for centering as will be later explained. At the other end a small ridge about ¼ in. wide was provided around the bore, this being finished and forming a seat for the cylinder head, gas tightness being obtained through the use of a copper-asbestos gasket. The foot projecting on either side of the side was machined on the bottom as well as to a shoulder, forming a ready means for securing perfect alignment with the crankshaft when placed on the bed.

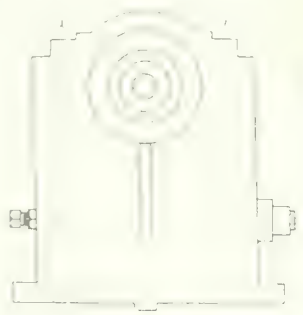
### Milling Feet

These feet were finished on the milling machine, this being the first operation. As the casting was located from these milled surfaces during the boring and drilling operations, it was necessary that, in the first operation, the rough casting be acurately located with respect to the bore of the cylinder. In Fig. 2 is shown the milling fixture, which is of the box type, the one end being provided with a hinged cover H which may be [illegible] K. To [illegible]

[illegible] these enter the cover when locked, effectively binding the two sides. Both [illegible] are pinned to the one shaft so that opening one will also open the other. Springs are placed behind them so that they are normally held closed. The cover is ribbed on the outside and carries the steel piece J which is turned out in the form of a cone and then relieved so that there is but a bearing at three points, this being used to center the projecting end of the casting on the outside.

### Centering and Clamping Mechanism

The mechanism at the other end of the fixture, which is used to perform both the functions of centering and clamping simultaneously, is shown in detail in Fig. 3. The projecting boss of the fixture is bored out to receive the steel piece B, to the end of which is bolted the cap D. Two keys G are rigidly fastened to the end of B and move in the slots in the slots in the main casting, thus preventing rotation as B is moved back and forth. Running through



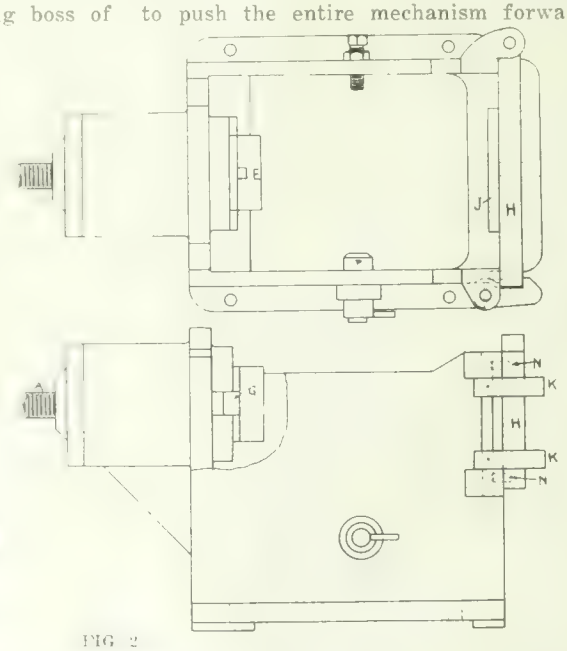


FIG. 2

B is the shaft A which is threaded on the outer end and passes through the nut C, also bolted to the main casting. The screw is rotated by means of the capstan nut which is provided with a locknut on either side. The other end is turned down and extends through the cap D with locknuts at the end. Against the shoulder and back of the hardened steel cone F are the two hardened steel collars. This cone bears against the three square centering pieces E which move in slots in the cap. These are held in toward the center by the springs and plugs shown. A heavy coil spring at the end of B tends to force same toward the fixture.

Two hardwood strips are placed in the bottom of the fixture so that the casting is brought to such a height that it will just slip over the piece D. The end is then snapped shut, and the plunger P, which has been drawn back, allowed to seat against the side of the hopper forceing the casting over against the adjustable stop screw at the other side, this being so set that when the cylinder is properly centered by the bore the sides are vertical. The drawing of this plunger in Fig. 4 is self-expanatory.

The screw A is now turned in a clockwise direction and this allows the heavy coil spring to push the plunger B forward until the hardened steel pieces G bear against the end of the casting when this will be pushed into the centering cone at the other end. Further movement of the screw will bring the cone F into contact with the three centering pieces and these will be pushed out against the inner surface of the barrel and accurately center the same. Any further movement of the screw will tend to push the entire mechanism forward and will tightly clamp the casting between the pieces G and the cone of the hinged cover.

Inserted tooth milling cutters were used

and these were accurately set by means of the finished surfaces 'a' at the end of the fixture. These surfaces, however, were not machined to the exact size but were somewhat smaller and a hardened steel gauge of the correct thickness was used for setting the cutters. In this manner the blades of the cutters never came in contact with the finished cast iron surfaces, with the consequent liability of destroying their accuracy. After taking the cut and running back the table it was but a moment's work to turn the plunger P, run back the clamping screw, throw back the cover H, withdraw the casting and insert another. After getting the cutters set to the proper position it was all routine work

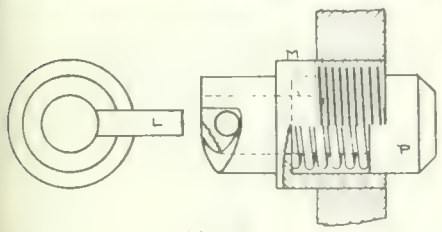

FIG. 4

and there was no opportunity of getting the casting in wrong. Centering the projecting end of the cylinder on the outside insured an even thickness of metal around the bore.

### Boring

The next operation was boring and this was carried out on a 24 in. heavy duty engine lathe. The tool carriage was run to the front and the fixture shown in Fig. 5 bolted to the carriage. This was quite heavy and well ribbed so there would be no distortion; permanent dowel pins were provided so that the positioning would be correct at all times. The boring bar is shown at 'b,' Fig. 6, being three inches in diameter and turned to one and one-half inches where the boring heads are carried. A draw-in bolt was provided through the spindle to prevent any possibility of the bar lossening on the facing cuts. The cylinder holding fixture was bored out at the forward end to carry the boring bar, a cast iron bushing being provided and the casting split so that a slight adjustment might be obtained with the clamping screws. This hole was bored out with a bar between centers so that it would be in absolute alignment with the spindle.

The other end of the fixture was

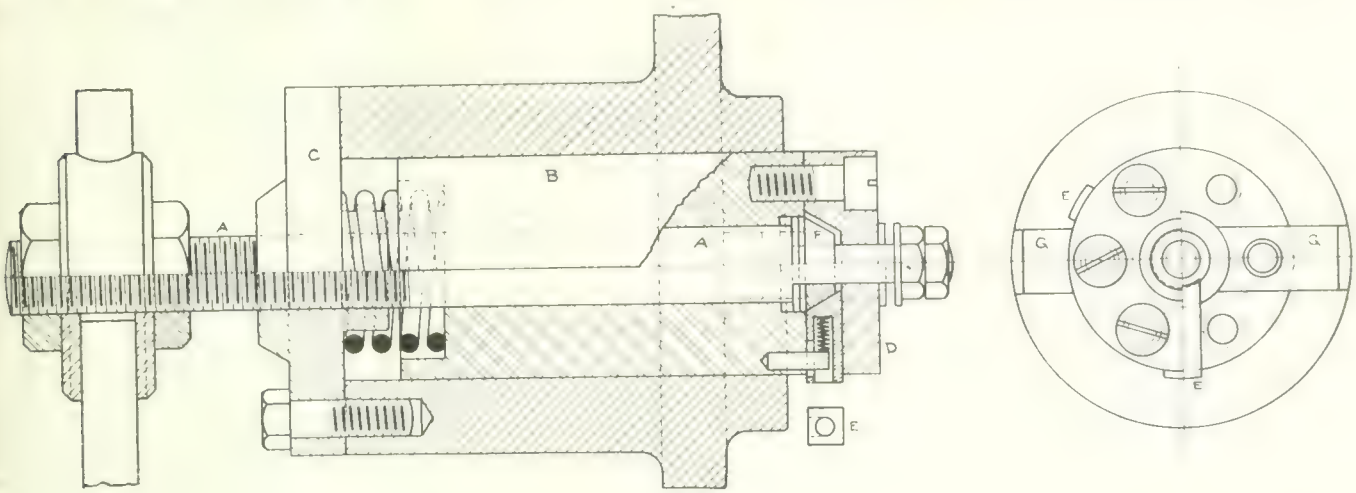

FIG. 3.

planed to accommodate the cylinder casting, these being placed with the neck toward the bar. Slotted clamps with springs beneath were used for clamping and a stud was placed in the casting to take the thrust of the heavy cuts. Two one-half inch steel pins in the body of the bar provided the drive for the boring heads, the holes being drilled slightly larger so that they could easily be slipped into position by hand while the bar was running. The bar turned about forty revolutions per minute and was operated continuously. The space between the end of the cylinder and the end of the bar was just sufficient for the boring heads. This was done to bring the start of the cut just as close to the bar support as possible. A roughing and finishing boring cut was taken through the cylinder before reaming; the construction of the boring heads being shown at 'c,' Fig. 6.

### Detail of Boring Heads

Six blades were used in each head, being unevenly spaced to prevent chatter; the blades were of high-speed steel, ¼ by ⅝ in. and were held in place by the ⅜ cold drawn steel pins which were set into the body at an angle of one and one-half degrees with the axis. The holes for the pins were first drilled and reamed and the slots milled with the pins in place. This insured an absolute fit between the blades and pins. In the two roughing heads ¼ in. steel pins were placed back of the blades to prevent their being pushed back under heavy cuts, though, in all probability, this was not necessary. The heads were taken off the bar as they came through the casting at the outer end. The head at 'd' was used to chamfer the end of the cylinder so that the piston rings would enter more easily.

The head at 'e' was for facing the end of the cylinder for the gasket fit. The bar was run entirely through the cylinder and the head slipped on but as the thrust of the cut was in the opposite direction from the boring heads it was necessary to make some provision for holding the head to the bar; this was done by the T-handle screw shown. The end of the bar being tapped, the screw was merely run until the shoulder rested against the steel plate on the head and which was used to support the cutting blades. To release it was only necessary to give the end of the handle a light tap and unscrew even though the bar were turning in the same direction. This head was of cast iron as the service was fairly light and was provided with a bearing in the bore of the cylinder only for a short distance at the center, the relief enabling the blades to be ground in below the diameter of the bore.

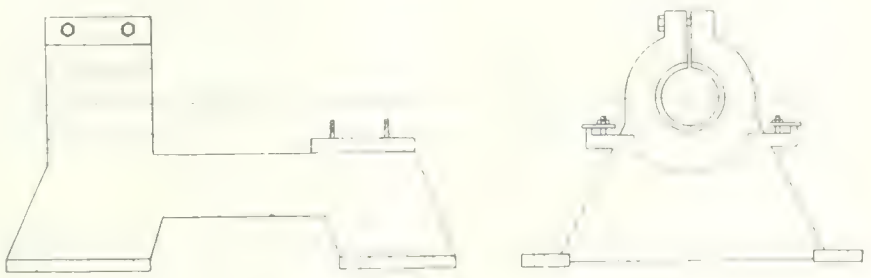

FIG. 5

### Output Capacity

In a test run on a small number of

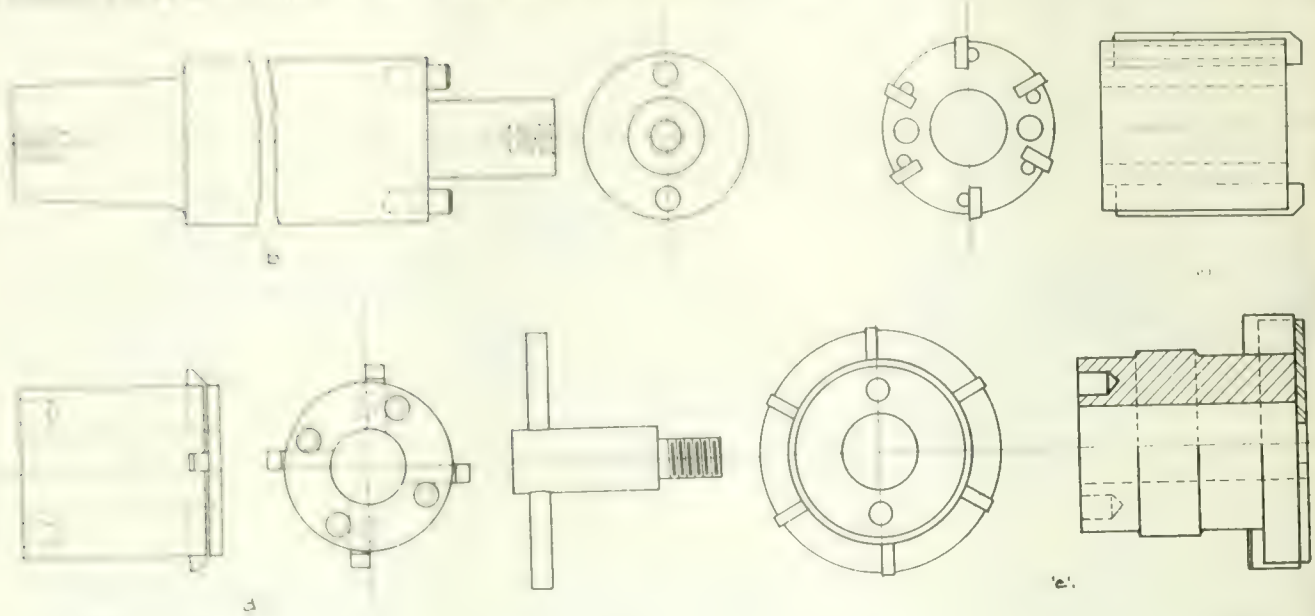

FIG. 6.

what bettered. The rigidity of the tools and fixtures enabled heavy cuts to be taken and the finish was all that could

## SHOT BLASTING H.E. SHELLS

By J. W. D.

JUDGING by the troubles which some firms are having in getting rid of the discoloration in the bore of the British H.E. shell, caused by the heating for the nosing operation, it would seem that a few remarks on the subject would not be out of place. Whether you use steel shot, angular grit or flint shot, there are two very essential points to keep in mind. The first is that the shot must be kept perfectly clean and free from grease. The second is that if a clean bore is expected from the shot-blasting machine the shell must be sent to this machine with the bores in a clean condition, free from grease or cutting compound. I have seen many firms who send the shell straight from a machining operation to the shot blast machine and expect it to collect all this dirt and grease and give them a clean bore, but this is not possible. The natural result of the above conditions is that the bore is covered with a film of a black greasy nature, which it is almost impossible to remove by washing, even with benzine. The only way to remove this is by polishing with emery.

In order to get away from this troublesome film of black grease, it is necessary to use a small quantity of shot; [illegible] twice a day or oftener if necessary. The shot may be cleaned by [illegible] it in a very fine sieve, then washing it in gasoline. Once it has been

This would also eliminate a lot of the varnish trouble, as varnish will not adhere properly to a greasy surface. Most shell makers would claim it ridiculous to say that varnishing a H.E. shell is as important as varnishing a piano or an automobile. The truth of the matter is that a shell is the most important, in as much as a badly varnished shell is very dangerous, while a badly varnished piano or automobile merely looks bad

## MARKING OFF GAUGE FOR SHELL BASES

By Munitions

GAUGING the thickness of the base of the shell forging preparatory to cutting off the surplus metal is an elementary but important detail. Owing to the greater difficulty that is experienced in the machining of the interior it is advisable to commence the primary gauging from the rough bore of the forging; it is therefore essential when cutting off the excess metal from the exterior of the base, that the thickness at this point be sufficient for finishing to the desired dimensions after the end has been cut off. A long U shaped gauge is generally adopted for determining the point for cutting off. The gauge shown in the accompanying sketch is made from a piece of ordinary angle iron, the finger portion that enters the bore of the shell being drawn down from an angle to a round shape to insure lightness and accuracy of operation. In constructing this gauge care should be taken that the point of the finger will be equi-distant from each edge of the angle iron, so that when the long straight portion of the angle iron rests on the outside of the shell the end of the finger will bear approximately on the middle of the interior base. To form a support for the center punch that marks the location for cutting off, a steel block is secured to the end of the angle iron as shown at A. With this piece fastened in position, the hole for the punch is put in and counterbored to receive the spring B that reacts against the collar on the center punch C. The pin D is inserted in the angle iron above the collar of the center punch to prevent the latter jumping out after the mark has been

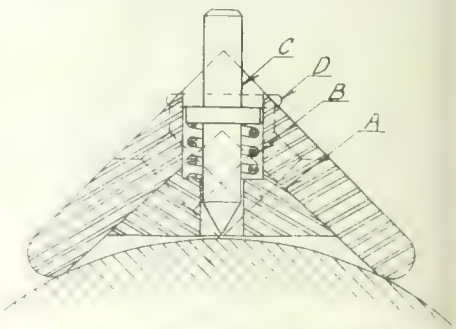

FIG. 7. CROSS SECTION THROUGH PUNCH.

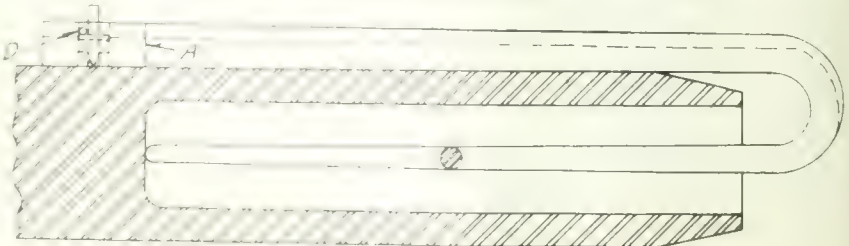

FIG. 8. SIDE VIEW OF GAUGE IN POSITION.

made. Fig. 1 is a general view of the device and Fig. 2 is a cross section through the center punch.

## VENTILATOR COWL QUERY

WE HAVE a number of ventilator cowls to make, similar to the one shown in the accompanying sketch. These are to be made of 16 gauge stock, in four sections, and with vertical seams. Owing to the necessity of hammering or swedging the pieces before the same are assembled, the writer would like to obtain some information on the development of the various portions on the flat sheet and the method adopted in the subsequent operations of forming the different sections to get an even and regular contour. Any data in this connection will be greatly appreciated.

* * *

## METHOD OF LAYING OFF COWL

FIG. 1 shows a ventilator cowl built up of four pieces with vertical seams. This type of cowl is much preferable from its visual effect to that made up with girth seams, and where pleasure yachts, passenger vessels and Government or naval craft are concerned the plate arrangement here featured is usually insisted upon. Fig. 2 illustrates the construction of the cowl, the layout of which may be drawn to any desired scale, or be made apply to any required size pipe.

Measure off A B equal to 20 inches, bisect at P and raise the vertical line V P equal to 40 inches. Draw the overhang V C at right angles to P V and equal to 18½ inches. With E as centre and radius (equal to 25 inches) draw in the arc C K F J so as to be tangent to the perpendicular A J raised from A B. Raise the perpendicular B L M.

Locate the point G, which is 4 inches above the line A B and 2 inches from B L M. With G as centre and 2 inches radius, strike the quadrant M N D tangent to B L M. Directly above the point G locate D, which is on the quadrant M N D. Connect by a straight line the

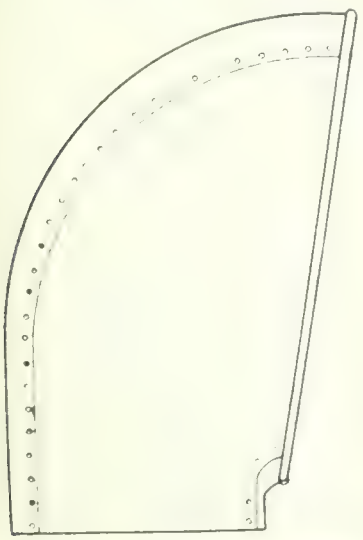

FIG. 1. VENTILATOR COWL WITH VERTICAL SEAMING.

points D and C, thus completing the outline of the cowl. Now divide the back into four equal parts as shown by A J F K C. Similarly divide the throat

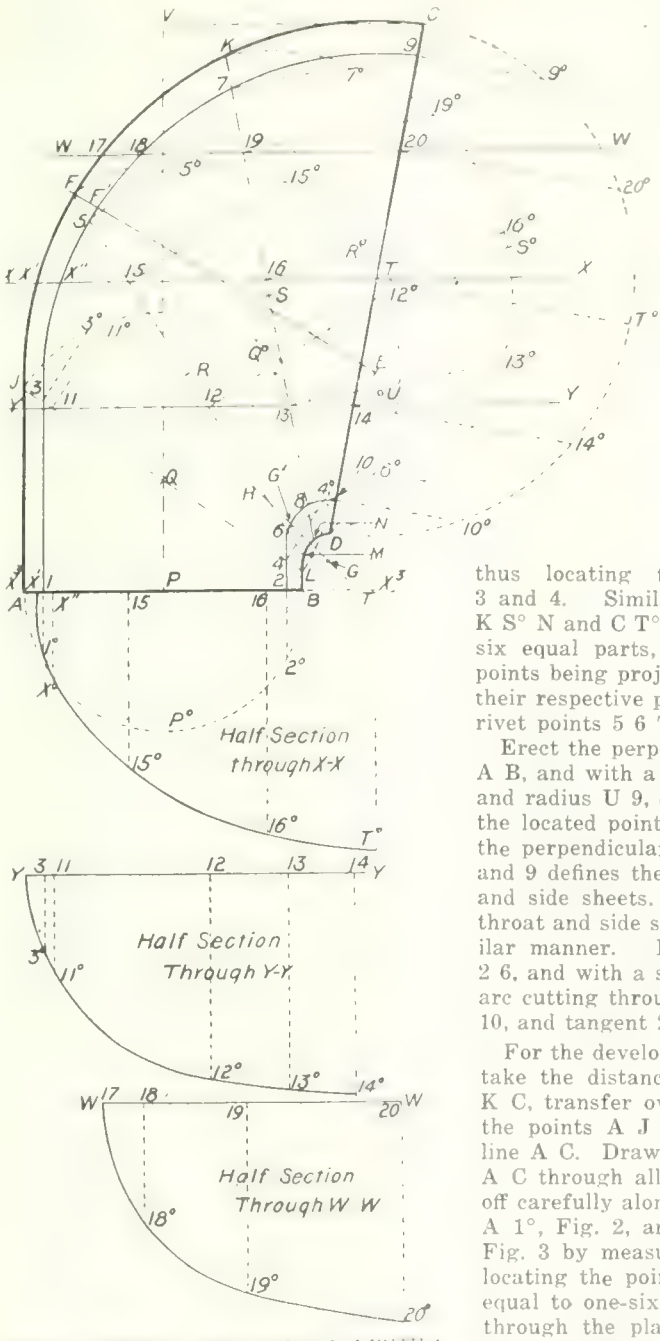

FIG. 2. GENERAL ANALYSIS OF VENTILATOR COWL CONSTRUCTION

sheet line into the same number of equal parts as shown by the points B L M N, and D. Connect these points by straight lines to their relative points on the back sheet line, as J L, F M, K N. These lines will be used as sectional planes and on them will be constructed the half sectional views.

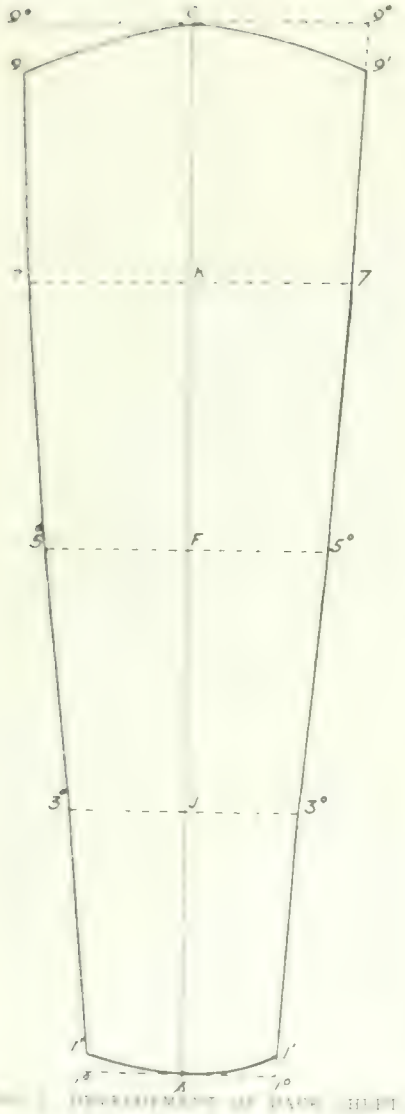
With P as centre and radius P A, strike the semicircle A P° B, thus defining the half-sectional view through the plane A B. Bisect J L at Q, then with Q as centre and radius Q J strike the semicircle J Q° L. Again, with R as centre, describe the semicircle F R° M. Similarly with S K and T C as radii, strike the half section views K S° N and C T° D respectively.

It is the usual practice in this type of cowl to make the back and throat sheets each equal to one-sixth of the circumference and the side sheets each equal to two-sixths. On this principle our patterns and templets will be developed. Divide the semicircle A P° B into exactly six equal parts and locate the end points 1° and 2°. At right angles to A B project the lines 1° 1 and 2° 2, thus locating the points for the rivet lines. Divide the arc J Q° L into six equal parts, the extreme points 3° and 4° being projected at right angles to the plane J Q L, thus locating the rivet line points 3 and 4. Similarly, the arcs F R° M, K S° N and C T° D are each divided into six equal parts, their extreme division points being projected at right angles to their respective planes, thus locating the rivet points 5 6 7 8 9 and 10.

Erect the perpendicular 1 3 to the line A B, and with a suitable centre as at U and radius U 9, describe an arc through the located points 9 7 5, and tangent to the perpendicular 1 3. The line 1 3 5 7 and 9 defines the rivet line for the back and side sheets. The rivet line for the throat and side sheets is drawn in a similar manner. Erect the perpendicular 2 6, and with a suitable centre draw the arc cutting through the points 6 8 4 and 10, and tangent 2 6.

For the development of the back sheet, take the distances A J, J F, F K and K C, transfer over to Fig. 3 and locate the points A J F K C on the straight line A C. Draw lines at right angles to A C through all these points. Measure off carefully along the curve the distance A 1°, Fig. 2, and transfer this over to Fig. 3 by measuring at each side of 1, locating the points 1° 1°, which will be equal to one-sixth of the circumference, through the plane having A B as diameter. Similarly measure J 3°, Fig. 2, and transfer to J 3°, Fig. 3. Again, transferring all the distances as F 5°, K 7° and C 9°, measured along the curve (or calculated), Fig. 2, to their respective locations in Fig. 3, an even curve is drawn in through these points by the aid of a flexible batten.

It will be observed that in Fig. 2 the line 1 3 5 7 9 is shorter than the line A J F K C; this, then, will have to be shown in Fig. 3. From the located point E, draw a straight line to F, locating the point F' where this line intersects the rivet line, Fig. 3. Measure carefully along the curve from this point F' to the point 9. This distance is then measured from 5° to 9' in Fig. 3. The dis-



transferred over to Fig. 4 and located on the straight line by the points B L M N D. Parallel lines at right angles to B D are drawn through these points. In Fig. 4, [illegible] is also equal to A 1², Figs. 2 and 3. Again, L 4², Fig. 4, is made equal to L 4², Fig. 2. Similarly the distance M 6², N 8², D 10², Fig. 2, are transferred over to their respective positions

these located points draw an even curve with the flexible wooden batten, as was done in Fig. 3.

It will be noticed that the rivet line 1 3 5 7 9 10, Fig. 2, is longer than the ellipse B L M N D. This extra length must be added on to the rivet line in Fig. 4. From the point G, through the centre of the quadrant M N D, draw the line G H. Measure from D to this intersection point on the quadrant, and transfer this distance over to Fig. 4, thus locating the line G H. From G¹, measured along the curve to 10, Fig. 2, transfer this distance to Fig. 4 by measuring from the line G H to 10¹. Similarly, transfer the distance G¹ to 2, Fig. 2, over to Fig. 4 as from the line G H to 2¹. Connect the points 2¹ B 1¹ and 10¹ D 10¹ each by suitable curves.

Fig. 4 shows the templet for the throat sheet, suitable laps to be added. The side sheets are developed in a slightly different manner. Transfer the outline of the side sheet as shown by 1 3 5 7 9 10 8 6 4 2, Fig. 2, to the similarly numbered outline in Fig. 5. Connect the points 1 P 2, 2 Q 4, 5 R 6, etc., Fig. 5, similar to Fig. 2. Measure off P 1″ and P 2″, Fig. 5, each equal to 1/6 of the circumference of which 2 B¹, Fig. 2, is the diameter, or measure along the semicircle the distance 1° 2°, Fig. 2, and place half of this at each side of point P, Fig. 5, to locate the points 1″ and 2″.

Calculate or measure off half the distance along the arc of 3° to 4°, Fig. 2, and place this distance at each side of the centre Q on line 3 Q 4, thus locating 3² and 4² in Fig. 5. Again, take the length of the arc 5° 6°, Fig. 2, and place half of this on each side of R on the extended line 5² R 6² to locate the points 5² and 6², Fig. 5. Similarly transfer the distances 7° 8° and 9° 8°, Fig. 2, to their relative positions to locate the points 7² 9¹, and 8² 10″. Connect the points 1″ 3² 5² 7² 9¹ and 2″ 4² 6² 8² 10″, as shown in Fig. 5. Measure the length of the line 1 3 5 7 and 9 and also the line 1″ 3² 5² 7² and 9¹. Take half the distance between these two lengths and locate the points 9² and 1² by measuring from 9¹ and 1″ respectively. Similarly measure to find out how much longer the line 2 4 6 8 10 is than the line 2″ 4² 6² 8²″. Take this difference and add half from 10″ to 10² and half from 2″ to 2². Connect 1² to 2² to locate the outline for the bottom of the side sheet.

To obtain the curved line 9² to 10², it is necessary to find out the points W″ T¹ and Y″. This is done in the following manner: Divide C D, Fig. 2, into four equal parts, and through these points draw the planes WW XX and YY parallel to the line A B. Project the points X¹ and X″ through, and at right angles to A B, thus locating the points X¹ and X″ on X¹ X³, which is shown on, and is continued on each side of A and B. Where the line F R M intersects the line X X, locate the point 15. Also locate 16 where K S N intersects the line X X. T is already located on X X. Project these points 15 and 16, and T down to and at right angles to X¹ X³. Continue [illegible] projection

section view through X X. On the elevation, Fig. 2, raise the perpendicular 15, 15° to its intersection of its arc F R° M. Take this perpendicular length and transfer to the line 15, 15° in the half-

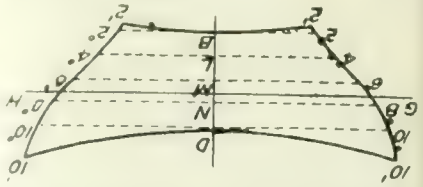


FIG. 4. TEMPLET FOR THROAT SHEET.

sectional view X X, Fig. 2. At right angles to K S N draw the perpendicular 16, 16° intersecting the semicircle K S° N at 16°. Transfer this length 16, 16° to 16 16° in the sectional view for this plane, which is X X. T T° is drawn at right angles to C T D, and its length transferred to T T° in the sectional view.

The distance X″ X° in the sectional view is equal to the distance through X″ on the line X X in the elevation. This distance is not shown in the elevation view, but it is obtained by using a little judgment. The distance through the point 5 is equal to 5 5° and through the point 3 is equal to 3 3°, so if X″ was midway between the points 3 and 5, it would be equal to the mean of the two distances 3 3° and 5 5°. But X″ is nearer to 5 than 3, so it will be seen that it is not difficult to get the distance X″ X° for the cross-section. An even curve drawn through the points T° 16° 15° 5° and X¹, in the section view, will define the half-section for the plane X X.

The sections for YY and W W are constructed in a similar manner.

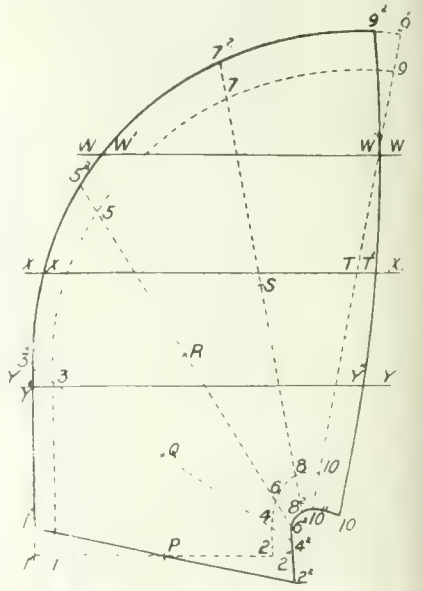

FIG. 5. DEVELOPMENT OF TEMPLETS FOR SIDE SHEETS.

The plane lines WW, X X and Y Y in Fig. 2 are transferred over to their proper positions in Fig. 5. The distance X° 15° 16° and T° in the sectional view, Fig. 2, is equal to the curve of the side sheet; it is, therefore transferred over to Fig. 5, measuring from the point X¹ along the line X X to the point T¹. With the three points 9², T¹ and 10² located,

the curve may be drawn in by a flexible batten. The points W" and Y" on this curve are located by taking the length of the curve 3° 11° 12° 13° and 14°, Fig. 2, and measuring this along the line Y Y, Fig. 5, from the point $Y^1$ to locate Y". To locate W", the distance 18° 19° and 20°, Fig. 2, is measured from $W^1$ along the line W W, Fig. 5. Five points are shown to locate the curve 9° W" $T^1$ Y" and $10^2$ and, although three points would be quite sufficient, the number is left to the option of the reader. If three points are chosen, it will be then only necessary to construct the cross-sectional view through X X in Fig. 2.

The heavy lines in Fig. 5 show outline of the templet, minus the laps, for the side sheet.

Sets or gauges of the sections of the various planes will be used for trying out the templets, during the process of hollowing or blocking out.

The continuation of the cowl below the line A B is a straight cylinder and is developed as such. This cylindrical course is, of course, fitted inside the cowl for water-shed purposes, using the line A B as the girth seam line.

## CLERGYMEN INVENTORS

IN referring to the work of the Rev. Robert Stirling, inventor of the heat regenerator, an English contemporary remarks that quite a large number of scientists and a good many inventors, some of marked eminence, have been in holy orders. The very earliest scientists, men like Roger Bacon and Schwartz, who vie for the proud distinction of having invented gunpowder, were naturally churchmen, because knowledge was practically concentrated in ecclesiastical circles. The first really eminent clergyman-inventor that we are able to recall was Lee, of Elizabeth's time, who in an age when mechanical knowledge was very small, laid by his invention of the stocking-frame, the beginning of a great industry. Cartwright, the inventor of another textile machine, the power-loom, was also a parson. Possibly these three, Stirling, Lee and Cartwright, stand out above all other mechanical inventors in holy orders, but in the domain of chemical science Priestly, a Unitarian minister, holds the highest place. Then we have Bell, who invented the reaper; Forsyth, a Scottish divine who produced an exceedingly ingenious percussion cap for fire-arms—it had a magazine of percussive pellets, and unluckily the explosion of one used to fire the others; Desaguliers— familiarly called amongst the old mining engineers of Cornwall, Desagulez, and well known as the philosopher of early steam engineers; Gainsborough, a brother of the famous artist, and an "ingenious mechanick;" C. W. Cecil, an inventor of a gas engine in 1820; the Abbé Arnal who, according to report, first proposed the use of the crank in the propulsion of ships, 1788, and, if our recollection serves us aright, Capel, the inventor of the mining fan. Other names occur to us. The Rev. Edward Berthon, Canon of Romsey, whose collapsible boat is well known, and Dr. Watson, Bishop of Llandaff, who was an ardent experimentalist in electricity and the first man to send charges, from frictional machines, of course, through considerable distances—through 10,000 ft. of wire at Shooter's Hill in 1748 or so was amongst them.

## THE STEAM GUN

AT a time when many novel devices are being employed to hurl death and destruction at an enemy, it is interesting to recall that amongst the inventions of that remarkable genius, Jacob Perkins, was a steam mitrailleuse, which astonished the good people of 1826 no little, but which was never used to any more serious purpose. Jacob Perkins was the pioneer of really high pressure steam. A mere 200 lb. or so was nothing to him; he preferred to employ 1,000 lb., and spoke lightly of a hundred atmospheres.

The pressure used in the gun was probably irregular, but according to Perkins' own statement it was at least 750 lb. The whole thing was extremely ingenious. The steam generator consisted of a stout steel tube 3 in. diameter and 6 ft. long, provided with headers into which a number of smaller tubes were welded. With the two headers were connected the ends of a coil of stout iron tube, 80 ft. in developed length, which was placed in a furnace. The coil and headers and pipes were filled with water, which circulated under the influence of the heat, and ultimately reached a very high temperature and pressure, the amount of which was controlled by a damper, regulated by the expansion and contraction of part of the tube system. When the generator was sufficiently hot water was injected into the space outside the tubes by a hand pump, and was rapidly converted into steam which was conveyed to the gun.

The gun was not more than a tube with a valve near the breech end, and just in front of the valve a hopper provided with a shutter for the bullets. On pressing the discharging lever the steam struck the bullet in the barrel and drove it out with considerable force. It was reported in 1826 that the gun had been brought to such perfection that it was exhibited before the Duke of Wellington.

Lead balls of an ounce in weight were driven at a range of 35 yards through an iron plate ¼ in. thick, or through eleven planks of hard wood one inch thick and placed one inch apart. But what most surprised the spectators was that the bullets issued in such rapid succession that a long plank was almost sawn in two longitudinally when the gun was swung round slowly in front of it. The piece with its generator was much too cumbersome and unwieldly for the field, but as an example of the use of very high pressure steam the invention is full of interest. Perkins was miles before his time if ever a man was, but his descendants are already beginning to see signs of the advent of much higher pressures than those in common use, even nearly a century after Perkins' time.—*The Engineer.*

## DEEPEST AMERICAN DRILL HOLE

A DIAMOND-DRILL hole in Sussex County, New Jersey, 4,920 feet deep, has recently been completed by the contract drilling forces of the Sullivan Machinery Co. A 2-inch diameter core was removed to a depth of 1,600 feet, beyond which tools removing a 1⅝-inch core were used to the completion of the hole. When the depth of 4,900 feet was reached the long line of rods required for drilling weighed 13 tons, and it took eight hours' steady work for hoisting them out, replacing them, and resuming drilling. It is said that the hole showed no deviation from the perpendicular. It required 20 months to complete the hole, which is 1,700 feet deeper than the deepest previous hole of which there is any record in North America. Only three or four diamond-drill holes have been put down in this country, it is said, exceeding 3,000 feet in depth.

## PEAT DEPOSITS IN CANADA

DR. EUGENE HAANEL, Director of the Mines Branch, has made a valuable report on the subject of peat, which is being given consideration in formulating a policy. Dr. Haanel estimates the total area of the Dominion overlain by peat bogs as 37,000 square miles, and of this total area the known peat bogs of Ontario, Quebec and Manitoba comprise 12,000 square miles, with an average depth of six feet. He estimates the 12,000 square miles will contain about 9,300,000 tons of peat, having a fuel value equivalent to about 5,400,000 tons of coal.

Seven bogs within convenient shipping distances of Toronto are estimated to be capable of producing approximately 26,500,000 tons of fuel; and seven bogs in the vicinity of Montreal could supply that city with 23,500,000 tons of fuel.

Five bogs along the Lower St. Lawrence, conveniently situated as regards water transportation to the City of Quebec, can, it is estimated, supply 16,250,000 tons of fuel and 5,700,000 tons of peat litter.

The bogs examined in Nova Scotia can produce 6,200,000 tons of fuel and 500,000 tons of peat litter, and those of Prince Edward Island produce 1,250,000 tons of fuel and over 1,000,000 tons of peat litter.

In Manitoba the aggregate fuel content of the bogs is estimated at less than 2,000,000 tons. One bog alone, however, it has been estimated, is capable of furnishing 2,500,000 tons of peat litter.

CONTENTS of a circular tank in Imperial gallons can be found by multiplying the diameter in inches by itself, the product by .7854, and this product by the length (also in inches), then divide the result by 277.

# Shell Inspection: What a Shell Inspector Should Know-II.

By Chief Examiner

*The profession of the eye with the increasing importance attached to quantity and quality of output under G.M.C. rules, is essential that inspection, to fulfill its purpose, must be applied with skill, honesty and intelligently. A little knowledge is sometimes dangerous if misapplied, and the author of this article endeavors to make clear the object of inspection, correct methods of applying it and incidentally the disastrous results attending ignorance or carelessness in performing the duties attached thereto.*

Final Inspection.

The final inspection of the shell is the most important of all, and the inspector must be careful and painstaking in his work. First see that the shell is clean. Dirt, grease and oil will not hurt. Machine oil collects dirt, and makes the scale slow.

After weighing comes the screwgauge. See that the threads in nose of shells are clean—not merely so-so—but CLEAN. Every little [illegible] and carelessness in this respect will mean considerable loss to the firm, not only in new gauges at $50.00 a time, but in rectifications, owing to the gauge being worn and misleading the inspector.

Before this should come the visual on fuse hole. See that the threads are clean and not damaged or torn in tapping; that the container seat is flat and not rounded at the edge; that the recess is not too wide; and that there are no burrs or sharpness at the top of the bore underneath the parallel portion below container seat. The screw gauge is the "low" and must go in the full length, without being forced at all. Its own weight should carry it home it must fit angle of fuse seat so that a .002 in. feeler can not enter, while a .001 in. feeler should not enter. After that, try the "high" to see that the diameter is not too great at the points of thread.

Now comes "bearing of recess from top of fuse-hole"; the H. and L. diamter of bore below fuse hole; see that the slots are equi-distant round the top of shell, and are deep enough; then pass on to the "body" rings H. & L.; the "cylinder" for concentricity of band with body; the form of "head" or "profile"; the "wall calipers" again; and the "dia. of driving band" (ring), "low." Now try the latter dimension "high" and at the same time, as you lift the shell out of the ring, turn it on its nose—base up-

for flaws which may have developed in facing off the base plate and see that

4 oz. hammer for looseness and listen

and clear. Then pass the "body" rings.

Second Visual

ing the band. Examine each shell visually, again, for the same defects as at preliminary, but especially for ghost lines if the shell has been in the varnish baking oven. The heat always brings these to the surface if they are prevalent in the steel. Next comes the "base distance"—the distance of base from driving band—H. & L.; the "width" of band, H. & L.; and the "form"; also "visual" on band for flaws and bruises and to see that the serrations are good. Then put the "body snap" over; then the length over all; and "base calipers." Don't forget to tap the band with the 4 oz. hammer, lightly, for looseness. If there is any vibration put on a new band. Everything being O.K., the shell now goes to be varnished and baked, after which the varnish inspector should see that it has an even continuous coat, with no "runnings," "overlappings," "crinkling," rust or grease spots, cracks, nor any foreign matter under or in the varnish.

It is now ready for the government men, and should be a correctly finished article if the shop inspectors have done their "bit" properly, honestly, and without fear or favor. Unfortunately, however, a man who is what he should be seldom holds his job, because he has of necessity to act in opposition to the foreman, who in his turn wants to get the shells shipped. Hence the necessity for government men who don't care what the foreman likes or dislikes.

### Regarding Proof Shells

Before leaving H.E. shell it would be well to say a word about the "proof." One shell is taken from each series, and on the success of this the fate of the whole series depends. If it fails, a second proof is sent, and if this fails, the series is rejected.

Think of it, you who inspect the shells for the firm—if the series is running at 501 and the proof fails, the firm stand to lose in machining alone somewhere around $1,000.00.

This proof is sent, in Canada, to Quebec to be proved. Two chisel cuts are placed half on the band and half on the steel in order to note the slip of the band. On the larger shells, the adapter carries chisel cuts also. Punch marks are made on the body for the "set up" and "set down" tests. The shell is carefully measured with micrometers at the punch marks, the wall thickness is gauged and the shell is filled with sand to the required weight. It is then fired into a sank bank. In the old country, proofs are fired from high tide to low tide, to avoid the concussion of the sand bank.

After recovery, it is again measured and gauged, the band and base plate—or adapter—are removed and the recess gauged. If any part of the shell has sprung, or given, or if the band or base plate have loosened, or if the band is not properly pressed into the groove and undercut; the shell is rejected, i.e., the proof has failed.

### Shrapnel Features

In the case of shrapnel,—the shell of which it is made contains more carbon than that used in high explosive, thus making it harder. It is further hardened, or tempered, at the machining plant. Forty per cent. of a shrapnel shell is filled with bullets, about the size of a marble, and the whole interior, after some of the component parts have been inserted, is filled up with rosin to prevent the bullets from moving about.

The inspection is, of course, different from that previously described, but the main principles are the same. Cleanliness, inside and out, is of the first importance. Defects in the manufacture of the steel, are much the same as in H.E., but in addition, "scale" is peculiar to shrapnel, and indicates defective material. Heavy scale denotes that the steel has been burned, and thereby deprived of its strengthening element—carbon. A further steel defect, peculiar to shrapnel, is the "water-crack." This is caused by uneven quenching, and also by water being mixed with the oil in tempering.

When inspecting shrapnel, examine the cup recess. This must be smooth and free from tool cuts and scratches. The cup must "seat down" correctly. The disc seating must also be correct because this component has an important function, and there must not be the smallest opening that would allow the rosin to get into the cup, and mix with the powder charge therein. The disc seating must have a square corner, no ridge or shoulder, and must on no account be eccentric. Examine carefully the walls; also the threads in nose, of which there must not be less than three. Look and feel for "pockets," which are sometimes caused at "heading-in," by the die becoming worn, or the shell not having been heated uniformly.

A tolerance is allowed in the thickness of shoulder, and a little lower down, but

absolutely none at the neck, or thinnest part of the wall. At this point, the thickness must be neither more nor less than .1 in.—1/10 inch. The shell must also be ground perfectly smooth externally.

**Components Assembly**

The driving band recess and undercut are examined in the same way as in H.E. shell. The cup and disc are inserted before heading or nosing in. The tube, which must be absolutely free from scratches inside, is screwed into the disc, and the center of the tube must be in the center of the shell. If not, the socket which is placed on the top end of the tube, and soldered there, will not fit. In this soldering, there must be no blow holes or other imperfections that would allow the rosin to boil out. Note the body just above the driving band, to see that it has not been squeezed when the D.B. was pressed on.

The cup is filled with black powder, at the loading plant—then the tube is filled up with three different kinds of explosive. When the time fuse starts work the flame passes down the tube, ignites the powder in the cup, and the bullets are forced towards the nose end, when the shell bursts at the neck. The entire nose of the shell flies off and the bullets spread out in the shape of a fan. A shrapnel shell always points towards the object at which it is aimed, when it bursts.

**Conclusion**

This article has been written in order to try and promote more interest in the actual inspection of shell than the mere "production at any cost." The better the article is made, the bigger the production, and the greater the safety of those who use them.

The writer met a returned soldier recently, who informed him that one of our own 4.5 in. shells hit him from behind, taking his right arm off just above the elbow. The driving band had slipped and the shell dropped too soon. Another returned man was the sole survivor of a gun crew—a shell had exploded prematurely, owing to a faulty base. There have been numerous cases where the fuse has blown out, the shell not bursting properly owing to the nose threads having been too large in diameter; also numerous cases where the fuse could not be screwed in because the diameter was too small. There is no time to make any repairs on the field of battle.

Every shell inspected by a government man carries the work mark of that man—his signature—covering the operation of inspection and impressed by him. This makes him responsible to his chief examiner, who is responsible to the assistant inspector for the district, who, in his turn, is responsible to his superior officers for his district. A good inspector or examiner is a man who is amenable to discipline, and who will let nothing interfere with his duty of inspection. All personalities must be put aside, and none of the good-fellow ideas taken advantage of. If the shell is right—pass it. If it is wrong—don't pass it, even if your own brother wants you to.

## ELECTRICITY FOR THE BRITISH NATION

ONE of the most far-reaching suggestions towards national reconstruction is set forth in an interim report made to the British Ministry of Reconstruction by the Coal Conservation Sub-Committee. The report is now issued to the public with the following preface by Dr. Addison:

"Minstry of Reconstruction.

"This report, which was presented to the Reconstruction Committee, is issued for the information of the public, and in the hope that the very important matters with which it deals may receive adequate consideration at the hands of all those likely to be affected by its proposals.

"It will be observed that important issues affecting municipalities and public bodies are raised in the report, and they will be explored in all respects by the Government before any action is proposed to Parliament upon the subject. In its legislative aspect the whole matter is being investigated by a Committee appointed by the Board of Trade, and presided over by Sir A. Williamson, M.P.

"(Signed) C. Addison."

The Sub-Committee proposes briefly, to supply all our industries with electrical power generated at big "superpower stations," not more than 16 in number for the whole country, and to eliminate or combine all smaller stations.

The primary object of the scheme is to economise our coal supplies. The amount of coal used in the United Kingdom for the production of power is 80,000,000 tons, at a cost of, say, £40,000,000 at the pithead. The Committee confidently states that, by an up-to-date and national scheme of electrification, 55,000,000 tons of this (£27,000,000 a year) could be saved. This, with a saving of the by-products now wasted by the burning of coal in open grates and boiler furnaces would effect a national economy of £100,000,000 a year.

**Economy Possibilities**

The most economical way of obtaining power from coal on a large scale is by generating electricity from it. The coal now used, says the Committee, would, if used economically, produce at least three times the present amount of power. An increased use of power is of the highest importance to the future prosperity of the country. It is the best way to increase the net output per head and, therefore, the prosperity of the worker. "The best cure for low wages is more motive power."

In the United States the amount of power used per worker is half as much again as in the United Kingdom. Leaving out of consideration workers in trades where the use of power is small or even impossible, it is probably nearly double what it is here.

It has been settled conclusively during the past 15 years that the most economical means of applying power to industry is the electric motor. In the factories put down for the production of munitions during the war, 95 per cent. of the machinery is driven by electricity, and it is only a question of time for all power to be applied in this way. The problem is not how to apply electric power but how best to generate it.

The development of electricity in this country has been hindered by the numerousness and the smallness of the electrical undertakings. At the present time the supply of electricity in Great Britain is split up among about 600 companies and municipal undertakings. The average generating capacity of such of these undertakings as possess power stations is only 5,000 horse-power, or about one-fourth of the capacity of one single generating machine of economical size, and about one-thirtieth of that of a power station of economical size. Technically and commercially the big generating station is admittedly the best.

**Proposed Reform Scheme**

The reform proposed by the Committee is to supersede all these small undertakings by laying down throughout Great Britain main trunk lines to be fed by some 16 "superpower stations."

The generating machines in these stations should be of large size, not less than 20,000 horse-power each. In more important industrial districts machines of as much as 50,000 horse-power might be used with even greater advantage. The generating station s should be on large sites with ample coal and water transport facilities. It is contemplated that at each generating station by-products might be extracted from the coal before it is used for the production of power, and that various electro-chemical processes which are essential for this country should be carried on near by. The sites for the stations must be outside, not inside towns. This would improve the health of the great industrial centres by the reduction of smoke, and would relieve the congestion of the railway lines in their neighborhood by practically abolishing the carriage of coal.

Various forms of electricity supply authority, both public and private, are considered, but the committee, on the whole, favors private enterprise. They are "impressed with the special need for initiative and resource in the management of the business of power supply, and they are of opinion that the freedom of range and keenness which are distinctive of private enterprise will be found to be in a high degree conducive to the fullest measure of success."

The 16 great power authorities, whether private companies or public bodies, would be controlled by a National Board of Electricity Commissioners. Existing plants would be handed over on equitable terms to the new authorities. In addition to the main generating stations, subsidiary generating plants would be set up wherever there was surplus gas or waste heat, as at blast furnaces and coke ovens, and the electricity so generated would be fed into the main-trunk system. In the same way, waste coal,

### Extreme Importance

As showing the importance of the scheme the report says: "It is scarcely possible to exaggerate the national importance of a technically sound system of electricity supply, because it is essentially one with the problem of the

dently (which is the position to-day) as it would be to have an efficient railway system if each municipal area owned its lines and long-distance transport was provided for by running power agreements. History shows that, in the early stages of railway development in this country, exactly the same process of amalgamation had to be gone through."

### REGARDING AERONAUTICAL INVENTIONS

All parties desiring to bring to the attention of the U.S. Government inventions pertaining to aeronautics, or suggestions for improvements of existing types of aircraft and their appurtenances, are requested to communicate with the National Advisory Committee for Aeronautics, Munsey Building, Washington, D.C., and to submit comprehensive outlines of the proposed devices, together with necessary drawings, data and the results of tests, if tests have been made.

All such suggestions and inventions are considered confidential, and where devices or suggestions of merit are submitted they are referred to the proper officials with suitable recommendations.

A special sub-committee on engineering problems has also been organized to assist in the work of examining inventions submitted.

Attention is called to the fact that many devices and proposals are submitted by persons unfamiliar with the principles and practices involved, hence such parties desiring to submit plans or devices should, as far as possible, secure competent scientific and technical advice before taking the time of the officials of the Government in examining devices or plans which clearly violate scientific laws or are contrary to the best aeronautical practice.

### BIG JUMP IN RADIUM

THE effect of war on prices has been more strikingly exemplified in the metal industries than anywhere else, particularly among metals which have practical use in war—although this includes nearly all of them. An article in the Railroad Red Book says the war pressure has been felt as keenly in the market for the rarest and costliest metal as in the commoner metals. Consequently the price of radium, which before the war was somewhere around $1,000,000 an ounce, is now approximately $2,800,000 an ounce.

Practically all the world's commercial supply of radium comes from the carnotite beds of Colorado and Utah, which also yield the rare metals uranium and vanadium. Even these deposits, however, are limited in extent and are difficult to work, and some of them are being worked out, so that the output of radium is likely to decrease rather than increase. Last year from 1,500 to 1,800 tons of carnotite ore was mined in Colorado, and this was considerably less than the quantity the previous year. The amount of radium extracted from a single ton of ore is infinitesimal.

### VOCATIONAL TRAINING FACILITIES INCREASED

ADDITIONAL machinery is being added by the Military Hospitals Commission to the equipment in the Calgary Institute of Technology and Art for the purpose of affording more returned men the opportunity to take up electrical and mechanical engineering.

The constantly increasing number of men returning from the front makes it imperative for the vocational training centres to be ready to receive them and grant them at once the training necessary to fit them to return to civil life.

In British Columbia, the vocational training facilities at the Shaughnessy Convalescent Hospital in Vancouver are being increased by the addition of twelve extra class rooms, while at Fairmont the equipment is to be supplemented by the addition of a big machine shop and drafting room. Accommodation will also be made for a large shoe repairing department.

#### Re-educational Centres

Provision for a centre of vocational re-education in Fredericton, N.B., is also being made in the fine vocational building now under construction there.

In carrying out its vocational re-education powers the Military Hospitals Commission has provided as wide a variety of courses as possible at all centres. The policy has been adopted, however, of developing centres of re-education with special equipment at important points as follows, Halifax, Montreal, Toronto, Guelph, Winnipeg, Calgary and Saskatoon.

Centres of re-education for agriculture are being developed at Guelph, Winnipeg, Saskatoon and at Olds, Alta., where the Provincial Department of Agriculture placed one of its agricultural high schools at the disposal of the Commission.

SIMPLICITY in cutting tools, so as to make them easy to sharpen and easy to replace, is the basis of good design. The designer should resist the temptation to allow his ingenuity to run away with his judgment. "Ingenious" tools spend most of their time in the tool room being kept in repairs, and the greatest production is nearly always obtained from a lay-out of a simple nature which is easily understood and taken care of by the operators.—Herbert.

ONE of the biggest difficulties connected with the quantity production of ships is the question of rivet driving. An idea of the magniture of the task may be obtained when it is said that if a concern were to build one ship a week, a weekly number of 650,000 rivets must be driven. When we consider that the best rivet drive is by a company which drives 250,000 per week, and the next best is by the three largest shipyards on the Atlantic coast, the magnitude of the task involved in driving 650,000 rivets in one week may well be imagined.

Vol. XIX. FEBRUARY 21, 1918 No. 8

## DEVELOPING PRESENT LABOR FOR FUTURE REQUIREMENTS

THE question of an ample supply of skilled labor wherewith to maintain Canada's industries in a desirable state of efficiency, both as to quantity and quality of output as well as variety of product, assumes an increasing importance with every month's continuance of the war.

The great activity in plant extension three years ago was accomplished by a plentitude of funds previously unavailable to most of our manufacturers, and the chance of thus securing high grade equipment was wisely taken advantage of. Had the same conditions obtained with the labor supply as with plant equipment, the prospects of successful competition in the future with world competitors would be very much brighter.

That we did not suffer more severely from the lack of really skilled labor was due to certain peculiar features of the situation—first, the type of product; second, the development of special purpose machines to suit unskilled labor; third, the availability of much skilled help from the United States.

The first two of these conditions will continue during the war only, while the third has been gradually disappearing since the States entered the war a year ago. It is stated that the call to arms there by both volunteering and conscription will soon have reduced the technical school attendance to one half, instead of it being doubled to meet the country's regular requirements. It is also stated further by the same authority that despite the present cessation of work in many lines and the lack of available capital for important projects of a peace character, the manufacture of war supplies has absorbed the young graduates of technical schools to such an extent that there is already a marked dearth of such assistance, which will become more and more accentuated as demand increases with military activity.

When one considers the enormous increase of Canada's machine shop products now over those of 1914, the industrial disturbance which must accompany anything like a return to pre-war outputs will result in much hardship, probably of a temporary nature only but sufficiently undesirable to make it the duty of both employers and employees to maintain themselves in a state of preparedness.

In reverting to peace products the phases of transition will probably be the exact reverse from those mentioned above. The type of product will become diversified instead of specialized; the completeness of design and finality of operation pertaining to one particular type of shell enabled exact methods of production to be outlined rapidly and effectively as each successive type of shell appeared. The specifications were placed on the producer's desk with, so to speak, instructions to go ahead.

Such will not be the case later; the manufacturer will have to find out what is wanted, may have to supply the necessary technical ability to design special products to meet varying demands from different countries, and his desire to go ahead and shove stuff through the factory like shells will be governed by his ability to dispose of them.

The fact that such conditions are more than probable causes further interest in the labor question, especially as to the availability and adaptability of women workers. This is a direct outcome of the second feature mentioned above, viz., the special purpose machine. It has been too frequently and too rashly assumed that because they have made good on shells they will make good on any class of machine shop work, but careful consideration gives pause to such anticipation.

The women who are making good now are not the same type as those who jumped into the game for the sake of temporary adventure coupled with high wages then prevailing. Conditions more nearly approach a normal state and the fashion-plate and society debutante are now eliminated along with their unsettling influence and unjustified usurpation of jobs which were a necessity for less favored individuals.

The amount of woman help thus permanently available is not sufficient in quantity or possessed of mechanical instinct or adaptability to permit any neglect by employers in regard to training and educating their present help. The necessity for immediate action becomes more evident when the improbability of the supply of help from the States again becoming plentiful is noted.

Because of its assumption of a man's share of the Allies' burden, financially and physically, the share which the American Republic will take in the work of reconstruction will be great in proportion and the probable stay abroad of many of the forces for such work in civilian capacity will prevent any available surplus at home.

It is therefore incumbent on all of our manufacturing firms, engineering or otherwise, to do all in their power to stimulate the interest of their employees in all branches of their work. Opportunities for machinist experience in shell shops are somewhat limited under present conditions, but the strong probability that an employer will need these men in the future, and need them plus, makes the question of present training and education a most vital one.

The greatest stimulation to study by shop hands is the knowledge that the management is watching their progress and that advancement is largely influenced by results attained. Firms who undertake educational work even in a limited way are more likely to be regarded with some degree of sentiment by the students, and when shells are forgotten and a hundred different things have to be investigated and produced, the firm which has the allegiance of its employees as a result of judicious apprenticeship and class work will be in an enviable position compared with those who take a chance on transient labor. The losses due to inefficient methods of utilizing permanent help and high proportions of floaters are enormous throughout the industry and employers owe it as a duty to themselves to reduce such losses by aiding in the gradual and complete improvement of their employees, physically and mentally.

# Milder Weather Affords Welcome Relief to Manufacturers

*Washington To Restrict Higher Copper Price Desired By Producers Machine Tool Market Quiet*

**THE temperature, although somewhat easier, is not yet [illegible]. The improvement in the weather has been of material assistance in the movement of freight but there still remains to be much [illegible] before the congestion is materially relieved. The coal situation, in the west and east, is coming in from the [illegible] Strict economy, however, must still be exercised in order to conserve available supplies and head off further drastic restrictions in consumption of fuel. The steel plants will benefit by the milder weather both in regard to easier operating conditions and heavier supplies of fuel. No substantial relief, however, is to be expected until next month when conditions will be more favorable. Advices from Washington state that restrictions are to be placed on the manufacture of steel for export. While this may not affect Canadian consumers engaged on war contracts, other consumers will likely be affected. The situation in the iron and steel trade in the States has not improved materially and the operations are still considerably below capacity due to the traffic congestion. The pig-iron situation is unchanged. The non-ferrous metal markets are devoid of any particular interest except that the price of zinc has been officially fixed by the United States Government. The copper market continues steady at unchanged prices. It is reported that an agitation is to be started for higher prices for copper in order to stimulate production. There is practically no spot tin on the market and some time must elapse before conditions show any material improvement. The scrap metal market is very dull and business quiet. Indications point to a continuance of prevailing conditions for some weeks. There has been little enquiry for machine tools and the market is quiet. Deliveries from United States builders are becoming more backward and prices are still very firm with an upward tendency on many lines.**

MONTREAL, Que., Feb. 18, 1918.—Owing to the fact that the first of the embargoes was ushered in with a heavy snowstorm in certain sections of the country, the reports that have been made regarding the results of the conservation order have been of a very encouraging character. The release of cars will relatively assist the railroad transportation problem. Disorganization, however, has been so general that it will take some little time to again return to normal operating conditions. To conserve the available ocean tonnage, shipping is being more and more confined to those essentials that are of primary importance for the successful prosecution of the war. Registration and inventory of labor resources with the purpose of utilizing the same to the best possible advantage, is being contemplated by the Government and the officials are now working on the details for putting the scheme into operation.

### Steel

The paralyzed condition experienced throughout every department of industry during the past two months, is showing [illegible] owing to the more moderate weather, which has materially assisted in relieving the congestion. [illegible] conditions are noted in furnace operation, as coke and [illegible] moved more [illegible] that the worst of the heavy weather is over, and from now on the railroads will be [illegible]. Steel production has shown a slight improvement but freight embargoes and accumulation of freight at various terminals [illegible]. New regulation in this respect has added to the nervous tone of the situation. As a result the mills are reluctant to accept orders other than those for Government requirements. Everything is being done to supply the demands of shipbuilders for the necessary plates and shapes, and in this connection capacity production is being urged. Work has commenced on the first of the fleet of merchantmen to be built by the Dominion Government; the first three vessels to be laid down will be of 4,350 tons, 8,200 tons and 3,800 tons, the first two at Montreal and the latter at Collingwood. The programme so far prepared includes about 40 ships, all of these to be laid down before the summer of 1919. Ten of the largest of these will be built on the Pacific coast but will be used in the Atlantic service during the war. Arrangements have been whereby an ample supply of plates will be obtainable from the American mills, contracts to be placed through the United States Purchasing Commission. Canadian railroads are still more or less congested and difficulty is still experienced in moving material to destination owing to embargoes and other troubles. Dealers report a good demand but are unable to accommodate customers owing to the inability to secure shipments of material. All quotations are firm and unchanged.

### Metals

The general tone of the metal situation is practically unchanged although strength is shown in some directions. Copper is well maintained but domestic consumers are operating under great difficulties. Tin is the center of interest and has again advanced, giving the situation a very strong tone. Spelter is inactive but a shade stronger. Lead has advanced on a quiet demand. Antimony and aluminum are both quiet and weaker.

**Copper.**—Although the available supply of copper is sufficient to meet all essential requirements, there is apparently little surplus for domestic use, and producers are showing some reluctance to release any of that held in stock owing to the possible contingencies that may arise, feeling that it is well to carry an over supply rather than be short. No doubt many consumers will be inconvenienced through this action of the refineries but it is well to recognize the fact that at any time heavy demands may be made for immediate quantities of metal. The local situation is relatively unchanged with no features of interest. Dealers report a steady market with quotations firm at 32c and 31c per lb.

**Tin.**—Further advances on the London market and the continued difficulty experienced in the obtaining of permits to ship tin from England and other eastern points had added to the strength of an already strong situation, which has been reflected in the market that prevails in the United States and also Canada. The demand for tin is quite heavy but the available supply is insufficient to meet all requirements, and therefore only the more essential needs are being supplied. Dealers, however, are in a little better position as the commandeering of tin is not so frequent. The New York situation is still very unsettled and quotations are generally of a nominal character but stronger than those of a week ago. Dealers here report considerable difficulty in obtaining supplies but are able to secure sufficient for all essential requirements. Quotations of 83½c show an advance of 4½c per lb.

**Spelter.**—The question of a fixed price on spelter is still deferred by the American Government and the market is more or less unsettled as a result. The situation, however, has taken on a little strength and prices are somewhat firmer. New York prices are maintained at

slightly below 8c. Local dealers are asking 11c, this being an advance of ½c over that of last week.

**Lead.**—No developments of special interest have transpired in the lead situation but the strength of the market can be indicated in the fact that the Trust price of lead in New York has been advanced ¼ cent per lb., to the base price of 7c; the market is, however, not active and the demand is quiet. Dealers here are quoting 9¾c or an advance of ¼c per lb. over last week.

**Antimony.**—The market is quiet both here and in New York, with an easier tone in the American situation, the quotation of 13¾c representing a decline of ¼c per lb. Dealers here continue to ask 18c but report a weak and declining market.

**Aluminum.**—The market is inactive with an undertone of weakness; the demand is light on the market quotation of 55c per lb., a decline over last week of one cent per lb.

### Machine Tools and Supplies

The demand for machinery has been slightly better than the previous week but the activity has been confined to equipment of a general character; munitions equipment is not very active although some little business is reported. Shipbuilding machinery has had a very fair week but tools requiring to be imported from the States are exceedingly difficult to obtain owing to the abnormal demands on all classes of machinery in the States and the necessity of securing shipping licenses before tools are permitted to leave the country. Canadian manufacturers are taking a greater interest in the production of such tools as are required for general domestic purposes and greater activity has been noted in the production of the recognized standard tools for general purposes. A Montreal firm is making preparations to manufacture a high grade type of tool room lathe, and hope to have the same on the market within a few months. The restrictions that are being placed upon the shipment of machine tools from the States will undoubtedly stimulate the production of such tools that have, up till now, been manufactured in America. Considerable business is being done in partly used machinery. Conditions in the supply market are about normal as the requirements for munitions operations and shipbuilding maintain a steady demand for small tools and general machine shop supplies.

### Scrap

The long expected regulations and the fixing of prices on certain scraps has at last materialized, as the American Government has adopted a schedule in relation to operations on some of the more important materials. A fixed price of $30 per ton has been placed on heavy melting steel, old iron car wheels, and No. 1 cast iron. A price of $35 per ton on low phosphorus steel, re-rolling rails, old steel wheels, No. 1 R. R. wrought iron, and $40 on standard low phoshorus steel. Cast borings and machine shop turnings have been set at $20 per ton. Dealers are permitted a commission of 3½ per cent. over these prices, when operating with consumers. The Canadian market has become a little steadier owing to these developments but activity is not pronounced; prices are comparatively firm in old iron and steel but old metals have a stronger tendency. No. 1 red brass turnings are now quoted at 16c per lb., an advance on the week of 2c per lb. Stove plate is stronger, the current quotation of $19 per ton being $2 higher than last week. Scrap zinc has advanced one cent. over that quoted last week, dealers asking 6½c per lb. Heavy lead shows an advance of 1½c, the quotation being 7c per lb.

## Toronto

TORONTO, Ont., Feb. 19.—Favorable weather conditions have enabled the railways to make a successful drive on fuel shipments, with the result that the situation locally has considerably improved and the threatened coal famine has been broken. There has also been a good movement of all kinds of freight, which will help to relieve the congestion. There is still a great deal to be done, however, before any permanent relief can be effected. Reports from Buffalo state that the Canadian market will likely suffer from a shortage of soft coal and that the situation will be serious. Supplies are understood to be far short of requirements in that city and the quality is often poor.

### Iron and Steel

Conditions in the iron and steel trade have somewhat improved, but not to a sufficient extent to justify the hope that the shortage of steel will be materially relieved in the near future. The improved weather has enabled the railways to tackle the freight congestion, but owing to the shortage of cars progress is rather slow. The steel companies are still suffering from lack of efficient transportation facilities and are not getting sufficient supplies of raw materials, nor are they able to ship the finished product as rapidly as is desirable. Operating conditions have improved somewhat, which should result in an increase in output. The export demand continues satisfactory principally from customers in India, New Zealand, Australia and South Africa, but shipping space is limited, and shipments are slow in moving. If it was not for the shortage of tonnage the export trade would be considerably heavier. At present shippers are handicapped by traffic congestion and lack of tonnage.

The American Government is discouraging the manufacture of iron and steel for export. Manufacturers have been notified not to produce export material until export licenses are secured. The principle involved is that iron and steel products have been placed on the conservation list. Incidentally this gives the Government a measure of control over prices at which commercial steel for export is sold. Technically it does not come under the set price regulations, the principle of set prices having been agreed upon last September to cover material bought by the United States Government, by the Government's Allies, and by the general domestic trade. The above will probably not affect Canada in so far as war work is concerned, but will likely lessen the supply of material available for consumers not engaged upon war orders. Traffic conditions across the line continue unsatisfactory, and there is still a large tonnage of steel of various descriptions awaiting shipment from the mills, yards and warehouses. Practically every mill is up to the limit of its storage capacity in warehouse and yard. The steel industry in the States is estimated to be now operating on a 50 per cent. basis, and no decided improvement is to be expected for several weeks.

The merger talk connecting the Dominion Steel Corporation and the Nova Scotia Steel & Coal Co. seems nearer realization than former reports have been. It now appears likely that the Dominion Steel Corporation will be the controlling interest and that developments may be expected in a few weeks.

### Scrap

The scrap market is still very unsettled and depressed and the freight congestion continues to curtail business on account of the difficulties of shipping and receiving material; no decided improvement is expected until the spring, when conditions generally will be more favorable. Prices of steel and cast iron scraps alone are firm, although unchanged, and stocks of these materials are low. There is not much of a demand for brass or copper scraps, and prices of these materials have a lower tendency.

### Machine Tools

This week has been a quiet one in the machine tool market. The demand for machinery for munitions is dull and consists of a few single tools for replacements or increasing production. There have been a few scattered inquiries for equipment for shipbuilding. Considerable difficulty is still being experienced in getting some lines from the United States on account of the heavy demand for machine tools in that country. The situation in regard to deliveries is becoming more acute, as the builders have more business than they can conveniently handle. Prices are still very firm, with an upward tendency.

### Supplies

Business in machine shop supplies is fairly active and prices are holding firm. Difficulty is still being experienced in getting some lines of supplies on account of the raw material situation, although no shortage in any particular line has been reported. Canadian crude oil has advanced, but there has been no change as yet in prices of gasoline or other refined products.

### Non-Ferrous Metals

There have been no developments of particular importance in the non-ferrous

last week. The copper situation is unchanged. [illegible] of copper in the United States has been curtailed in recent weeks by the severe weather, but a new wave of activity is starting which is expected to result in the largest output of copper, each month from now on, that has ever been recorded. Lake and electrolytic are unchanged at 29c and casting at [illegible] per pound.

**Tin.**—There is no improvement in the tin situation. Spot supplies of tin continue extremely scarce and command almost any price holders care to ask. From now on the requirements of customers on this continent will be filled direct from the Far East. As deliveries from primary sources to New York and Eastern Canada take at least 90 days, it may be several months before any real relief is experienced from the tin shortage. Quotations are entirely nominal at 80c per pound.

**Spelter.**—The maximum price of grade A zinc has been officially fixed at 12c per pound f.o.b. St. Louis, subject to [illegible]. A maximum of 14c per pound for plate zinc f.o.b. at plants and 15c per pound for sheet zinc f.o.b. at plants has been fixed, subject to the usual trade discount. The market is quiet and local price unchanged at 9½c per pound.

**Lead.**—The lead situation is unchanged, although an active buying movement would likely send prices up. At present there is no indication of any material fluctuation. Local price, 9c per pound.

**Antimony.**—The market has been rather unsettled by cheaper offerings from the Far East, but quotations are unchanged at 17c per pound.

**Aluminum.**—There is a better tone to the market, with more inquiry. Local price, 52c per pound.

## New York

NEW YORK, Feb. 16.—Several contracts for projectiles have been placed by the Government in the last few days and large additional contracts will be [illegible]. None of the shell makers have purchased any tools, but in anticipation of larger Government orders manufacturers holding Government orders have also bought shop equipment. Among the purchasers are the Standard Roller Bearing subsidiary of the Marlin-Rockwell Corporation, Philadelphia, and the Babcock & Wilcox Co., of Bayonne, N.J. Arthur Brock, Jr., Philadelphia, has purchased screw machines. The British Government has placed a contract for the manufacture of parts of the Rolls-Royce motor with the H. H. Franklin Manufacturing Co., Syracuse, N.Y. To execute this order the latter company has reduced its output of automobiles by 40 per cent.

Purchases of drills are about to be made by the Government for the manufacture of gas masks at the Long Island City factory, which is being operated under the direction of the medical department of the army, and is known as the Gas Defence plant. The Simplex Automobile Co., which is manufacturing airplanes of the Italian type, has bought a number of grinders. The Duesenberg Corporation, Newark, which has secured the Fiatt automobile plant at Poughkeepsie, N.Y., for the construction of airplane motors of another Italian type, is expected in the market for machine tools soon, and will later make heavier purchases when the plant extension at Newark, which is just begun, has been completed.

munitions are again buying machinery on a liberal scale. The Savage Arms Corporation has issued a list for several hundred new tools for installation at its Utica, N.Y., plant, by which output will [illegible] when the new equipment is in operation it is designed that the Utica factory will manufacture 300 Lewis machine guns a day. It is now turning out 130 guns of this type daily.

### Arms and Aviation

A new order for 9.5 in. shells has been given to the Picatinny Arsenal at Dover, N.J., and an order for the same size shells has been given to the A. P. Smith Manufacturing Co., East Orange, N.J. Word comes from the trade that the Pollock Steel Co., with a plant at Cincinnati, has been awarded another contract for 8-in. shells.

The Watervliet Arsenal has made a few additional purchases of tools in this market, and several private manufac-

**CANADIAN GOVERNMENT WAR PURCHASING COMMISSION**

**The following gentlemen constitute the new war Purchasing Commission. Sir George Foster, Minister of Trade and Commerce; Frank P. Jones, Montreal; J. W. McConnell, Montreal; James H. Gundy, Toronto; Charles McNaught, Toronto, and Joseph Gibbons, Toronto. C. A. Magrath, as Fuel Controller, and Hon. H. Laporte, as chairman of the War Purchasing Commission, are members of the board ex-officio. Sir George Foster is Chairman of the Board.**

### General Contracts

Inquiries are in the market for eight locomotive cranes for construction work on the powder plants which are being built for the United States Government by the Du Pont Powder Co., and large purchases of machinery as well as of small cranes will also be necessary for these various plants. Greater activity is evident in the demand for cranes, and there is increased competition among manufacturers for the business that is coming out; some of the larger companies can now make shipments in four to six months. The American Smelting & Refining Co. has bought a crane for shipment to its Chili, South America, copper works, and the Brooklyn Rapid Transit Co. is understood to have virtually closed for an electrical travelling crane, 85-foot span, for the Williamsburg power house.

Structural work on Government account is active, revised bids having been taken by the Signal Corps of the army on a number of hangars in units of 100, which will be built in France. It will be recalled that estimates of the steel required for the building of these sheds for the allies and the United States Governments amount to approximately 100,000 tons. According to trade estimates, fabricated structural steel work placed in January amounted to 80,000 tons. The official report of the Bridge Builders' Society will be available early next week.

## Washington

WASHINGTON, Feb. 16.—The United States is confronted to-day with conscription of labor. The labor shortage and growing numbers of strikes have brought the Administration face to face with the fact that there must be quick and drastic action if the full force of the industries of the United States is to be felt in the European war.

### Labor Situation Critical

There is well-founded rumor in Washington that President Wilson has become so aroused over the labor situation that he is inclined towards a proclamation conscripting labor. Such action would meet with violent opposition from labor leaders. Samuel Gompers, president of the American Federation of Labor, has appeared within the week before Congressional committees to tell them that there is no labor shortage, but there is maladjustment of labor. He contends that there have been no proper facilities for distributing labor to points where it is needed. Despite these protests of a plentiful labor supply coming from the labor leaders, it still remains a fact that industries throughout the entire United States are failing to meet their contracts because of an inadequate labor supply.

The labor situation, as it regards the shipbuilding industry, is the most vital question now confronting the Government. With a general strike among shipbuilders called on the Atlantic coast,

there seems to be a very well founded fear that the shipping programme of the United States will be seriously interrupted. A joint commission of members of the National Council of Industrial Safety and the American Federation of labor is struggling with the problem and attempting to reach a settlement which will stop any prolonged strike and tie up of the shipbuilding industries of the Atlantic coast, where the majority of the work in building a merchant marine is being done.

All foreign trade in the United States imports and exports are now under license. This step has just been taken in accordance with a proclamation issued by President Wilson and was determined on to form a part of the general programme of the Allies to release ships for transport service.

### Shipbuilding Query

The first keel for the portion of the American merchant marine to be built at Hog Island, Penn., was laid this week. At the same time President Wilson ordered a thorough investigation to be made to determine whether the charges of extravagance of Government funds at Hog Island are substantiated to a sufficient degree to bring criminal action. The investigations of the Senate Commerce Committee have brought out evidence that the American International Corporation estimated the cost of a shipyard of fifty ways at Hog Island at $21,000,000. Already more than $28,000,000 have been spent, and the plant is still far from completion, while only one keel has been laid for the fifty vessels which the corporation is under contract to produce. It has been testified that the total cost to the Government will be $42,000,000. Charges have been made of gross inefficiency, of thousands of laborers employed at the yard and under Government salary with no work to do. The Senate Commerce Committee will send a subcommittee to the yards to investigate during the coming week, and the Department of Justice has already started a separate investigation. There has been intimation from the Shipping Board that the contract with the American International Corporation will be cancelled and the Government will take over the task of finishing the yard, which was planned to be the largest shipyard in the world. In this plant lays the test of America's shipbuilding capacity. It has been characterized by experts as "the most stupendous task" in the history of industry, for according to plan it was to have been completed in less than a year, with ships being turned out in some eight months' time. There is every indication now that the project has at least failed in part. The officers of the American International Corporation declare they are on schedule, and they have had to forget costs in the interests of speed.

The industry of the United States is once more on a normal basis of six working days a week. The order of Dr. Garfield, Federal Fuel Administrator, closing all factories manufacturing non essentials or unengaged in any war industry, has been revoked. This has been brought about in part by the clemency of the weather and the untangling of railroad congestion, which has allowed coal to move more freely in the past two weeks than it has done at any other time since late fall.

### Concrete and Submarines

The United States Shipping Board is not going ahead with its plans without trying some experiments at least. Chairman Hurley has reported to the Senate Commerce Committee that the Shipping Board is now experimenting with concrete vessels. There are three ships of this construction now being manufactured, and if they prove to be seaworthy and practicable a number of contracts for concrete vessels will be let.

The Navy Department has announced that a new type of submarine destroyer is now being constructed at the Ford automobile plant in Detroit. This vessel will be of light draft and will be transported overland to the coast. It is stated that within a short time quantity production will begin and the little ships will be constructed in less than thirty days' time.

War for a reorganization of the war machinery of the United States still goes on in Congress. Speeches for a greater centralized power over the industries of the nation are still being made in both the Senate and the House. Little hope is extended, however, that the United States will at this time adopt the plan of a director of munitions.

The United States navy is asking for bids on a quantity of miscellaneous hardware. Manufacturers desiring to bid should write to the Bureau of Supplies, Navy Department, Washington, D.C., asking for schedules 1687, 1686, 1680, and 1688.

## Pittsburgh

PITTSBURGH, Pa., Feb. 16.—There has been no iron and steel market, in the ordinary sense of the term, for weeks past, because shipments of pig iron and steel were far short of contract obligations, and shipments were small because the railroads were unable to handle more material, and the railroads were in that position by reason of the weather. Hence the dominant factor in the iron and steel situation is the weather, and the important news of the week is that there have been seven days of very favorable railroad weather since last report, making a spell of favorable weather of 11 days to date, with temperatures averaging about 40° and scarcely any precipitation.

### Railroads Make Improvement

The railroads have made excellent progress in clearing up congestion. In tangible results, by way of there being heavier shipments of pig iron or finished steel products, the trade observes very little improvement, but that circumstance arises from the nature of the case. The railroad executive have addressed themselves to the clearing of congestion caused by loaded cars in yards and on sidings. A large amount of freight has been moved forward to destination and receipts at nearly all points have been heavy, but thus far the return of empty cars has continued relatively light. Obviously the moving of freight already en route was the most important work to undertake but the railroad executives were doubtless quite conscious of the fact that if a large increase in the supply of empty cars to shippers were effected they would be offered a correspondingly larger amount of freight to move.

Receipts of coke at blast furnaces the past week have been very heavy and have represented the major portion of the coke that was stalled en route. Shipments from Connellsville ovens have not increased materially. For the six days of the week car supplies in the coke region have been, respectively, 70, 30, 35, 40, 20 and 30 per cent. of allotments. Production of pig iron has increased very considerably while steel works operations have increased but slightly, and some pig iron has been accumulating. For weeks past there have been railroad embargoes that covered nearly all consuming points, and permits to ship through or into the embargoed territory have been very difficult to secure. Up to date there has been very little easing off in this respect, and shipments of finished steel from mills in the past week cannot be estimated at more than 60 per cent. of capacity. The average thus far this year is a trifle under that, about two-thirds of the material being war material and no more than one-third ordinary commercial steel.

By an order issued the middle of the week the "Garfield Mondays" have been canceled, and plants are now entirely free from the fuel saving order, which closed plants for the five days ended with Tuesday, January 22, and three Mondays succeeding. The original order contemplated closing for six Mondays in addition. While Fuel Administrator Garfield took the entire responsibility for the order, it is the firm belief in the trade that the railroad administration was really responsible for it, its rescinding being of course based upon better traffic conditions developed since.

### Steel Production

Reports of the American Iron and Steel Institute show that 29 steel making concerns which in 1916 produced 88.14 per cent. of the country's total output of steel ingots (disregarding castings) made 2,733,722 gross tons of ingots in December and 2,203,845 tons in January. Allowing for the producers not reporting, the figures indicate that the annual rate of steel ingot production was 38,340,000 tons in December, and 28,620,000 tons in January. The most conservative estimate admissible is that there is 47,000,000 tons capacity at present, and it is possible the capacity may really be close to 50,000,000 tons. Thus the production in January was at not

rapidly once the improvement is really [illegible] supply of pig iron for the steel works [illegible]

Shipments, and in turn production, may increase rapidly in the next few weeks and the question is whether there will be sufficient commercial demand to absorb the steel. Since the first of the year shipments have been at about 40 per cent. of capacity in war material and 20 per cent. in commercial steel, or 60 per cent. altogether. There is no occasion to make any great increase in the shipment of war steel, which has been at very nearly an adequate rate. With improved traffic conditions the demand for commercial steel may greatly increase, but it is rather questionable whether it could increase enough to furnish full employment to all the steel making capacity.

For some time export houses have found steel mills quite unwilling to quote on export business, and with such unanimity as to create suspicion that they were acting under more or less definite instructions. In the past week it has been announced officially that the War Industries Board has ruled that mills should not begin producing any export material for which an export license has not already been granted by the War Trade Board. This was followed by announcement in Washington yesterday that all foreign trade, both imports and exports, all commodities, was put under license. One object, of course, is to conserve merchant shipping space. Another object, doubtless, is to curtail unessential industrial activity, in which matter there are many who feel the Government has pursued altogether too lax a policy in the past. As to iron and steel, another object, which will be developed by the freedom or otherwise with which export licenses are granted, is doubtless to exercise control over prices, for the present set prices are by agreement made to apply to purchases by the Government, its Allies, and [illegible]

[illegible] that non-contiguous countries in

# Enlarged Canadian Trade Intelligence Service

**Under the arrangement made by the Minister of Trade and Commerce with Sir Edward Grey in July, 1912, the Department of Trade and Commerce, Ottawa, is able to present the following list of the more important British Consulates whose officers have been instructed by the Foreign Office to answer inquiries from and give information to Canadians who wish to consult them in reference to trade matters.**

CHILE—Valparaiso, British Consul General.

COLOMBIA—Bogota, British Consul General.

ECUADOR—Quito, British Consul General. Guayquil, British Consul.

EGYPT—Alexandria, British Consul General.

FRANCE—Havre, British Consul General. Marseilles, British Consul General..

INDIA—Calcutta, Director-General of Commercial Intelligence.

ITALY—Genoa, British Consul General. Milan, British Consul.

MEXICO—Mexico, British Consul General.

NETHERLANDS—Amsterdam, British Consul.

PANAMA—Colon, British Consul. Panama, British Vice-Consul.

PERU—Lima, British Vice-Consul.

PORTUGAL—Lisbon, British Consul.

RUSSIA—Moscow, British Consul General. Petrograd, British Consul. Vladivostock, British Consul. Odessa, British Consul General.

SPAIN—Barcelona, British Consul General. Madrid, British Consul.

SWEDEN—Stockholm, British Consul.

SWITZERLAND—Geneva, British Consul.

URUGUAY—Monte Video, British Vice-Consul.

VENEZUELA—Caracas, British Vice-Consul.

BRAZIL—Bahia, British Consul. Rio de Janeira, British Consul General.

# Canadian Commercial Intelligence Service

**The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Commissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.**

### CANADIAN TRADE COMMISSIONERS.

ARGENTINE REPUBLIC—B. S. Webb, Acting Canadian Trade Commissioner, Reconquista, No. 46, Buenos Aires. Cable address, Canadian.

AUSTRALIA—D. H. Ross, Stock Exchange Building, Melbourne. Cable address, Canadian

BRITISH WEST INDIES—E. H. S. Flood, Bridgetown, Barbadoes, agent also for the Bermudas and British Guiana. Cable address, Canadian.

CHINA—J. W. Ross, 13 Nanking Road, Shanghai. Cable address, Cancoma.

CUBA—Acting Canadian Trade Commissioner, Lonja del Commerci, Apartado 1290, Havana. Cable address, Cantracom.

FRANCE—Phillipe Roy, Commissioner General, 17 and 19 Boulevard des Capucines, Paris Cable address, Stadacona.

ITALY—W. Mc. Clarke, c/o H. M. Consul, Milan.

JAPAN—E. F. Crowe, Acting Canadian Trade Commissioner, P. O. Box 109, Yokohama. Cable address, Canadian.

HOLLAND—Ph. Geleerd, Acting Canadian Trade Commissioner, Zuidblaak, 26, Rotterdam. Cable address, Watermill.

RUSSIA—C. F. Just, Canadian Government Commercial Agent, Alexandrinskaia, Plosch 9, Petrograd. L. D. Wilgress, Canadian Government Commercial Agent, Bukhgolza Ulitza No. 4, Omsk, Siberia.

NEWFOUNDLAND—W. W. Nicholson, Bank of Montreal Building, Water Street, St. John's. Cable address, Canadian.

NEW ZEALAND—W. A. Beddoe, Union Buildings, Customs Street, Auckland. Cable address, Canadian.

SOUTH AFRICA—W. J. Egan, Norwich Union Buildings, Cape Town. Cable address. Cantracom.

UNITED KINGDOM—Harrison Watson, 73 Basinghall Street, London, E.C.2, England. Cable address, Sleighing, London. N. D. Johnston, Sun Building, Clare Street, Bristol Cable address, Canadian. J. E. Ray, Central House, Birmingham. Cable address, Canadian. J. Forsyth Smith, 31 North John Street, Liverpool. Cable address, Cantracom. F. A. C. Bickerdike, 4 St. Anne's Square, Manchester. Cable address, Cantracom. J. Forsyth Smith, Acting Canadian Trade Commissioner, 87 Union Street, Glasgow, Scotland. Cable address, Cantracom.

### CANADIAN COMMERCIAL AGENTS.

AUSTRALIA—B. Millin, Royal Exchange Building, Sydney, N.S.W.

BRITISH WEST INDIES—Edgar Tripp, Port of Spain, Trinidad. Cable address, Canadian R. H. Curry, Nassau, Bahamas.

NORWAY AND DENMARK—C. E. Sontum, Grubbegd No. 4 Christiania, Norway. Cable address, Sontums.

SPAIN—J. F. Roberts, Hotel Cuatro Naciones, Barcelona.

### CANADIAN HIGH COMMISSIONER'S OFFICE.

UNITED KINGDOM—W. L. Griffith, Secretary, 17 Victoria Street, London, S.W., England Cable address, Dominion, London.

# NOSING DIES

## *For All Sizes of Shells*

Recently we told in this space of a Nosing Die in use in our own shops which had nosed 35,000 shells, and was still working. This die is still in use, and doing good work.

We now publish the following letter from one of our customers as a further proof of the long life of our CHILLED IRON NOSING DIES.

Messrs. March & Henthorn,
Belleville, Ont.

Gentlemen,—

We have been using your Nosing Die in our shop for six months past and they have given better satisfaction than anything we have yet tried. The die which we are now using has nosed nearly 10,000 shells and it is as good as ever and no doubt will nose a great many more.

We would say that the material you are using for these dies at present seems to be very good, and we are getting the same satisfaction.

Yours truly,

Name given on application if required.

We make these Chilled Iron Nosing Dies for the various sizes of Shrapnel and High Explosive Shells, and also for the .75 Millimeter French Shell.

We also make Chilled Iron Sleeves for Forging Billets for the .75 Millimeter Shells.

## ENGINEERING

[illegible] concrete factory to cost $150,000.

**Winnipeg, Man.**—The Central Tools & [illegible] such as chisels, punches, sub- [illegible] smith supplies, etc.

**Hamilton, Ont.**—[illegible], manager of the United Gas and Fuel Co., stated recently that he would bring up at a meeting of the directors of his company the question of reviving the coke oven proposition.

**Hamilton, Ont.**—The Provincial Government estimates include $92,027 for the asylum. Of this sum, $40,000 is for an additional building, $10,000 for a new boiler house, and $3,000 for fire alarm system and fire protection.

**Montreal, Que.**—The Southern Canada Power Co. is contemplating the construction of about 100 miles of high tension transmission line and has called for tenders on poles, cross arms, insulators, cross arm braces, wire and other materials.

**Montreal, Que.**—Through an error in our issue of Feb. 7th it was stated that the plant of the St. Lawrence Welding Co., 138 Inspector St., had been destroyed by fire. The actual damage to the building was confined to a small portion of the roof, and no material inconvenience was experienced in the operation of the plant.

**Toronto, Ont.**—The Provincial Hydro Electric Commission have made an important departure from the old policy with reference to the erection of steel work in new buildings and in the extension of their transmission lines, and in the future this work will be done under the control of the commission instead of private steel companies.

**Ojibway, Ont.**—Approved by Dr. J. W. S. McCullough, chief provincial medical health officer, a complete waterworks plant for Ojibway, to have a daily pumping capacity of 7,000,000 gallons, will be constructed this spring. The Canadian Steel Corporation has decided to go ahead with the plan, as negotiations with Walkerville and Windsor Water Commissioners have got progressed rapidly.

**Weston, Ont.**—Building operations on [illegible] factory of the K. and S. Can- [illegible] at Weston, have re-

**Port Arthur, Ont.**—The Port Arthur Pulp Mill commenced the manufacture of pulp last week. The mill will soon be [illegible] 60 tons of pulp daily to the paper mills.

**Toronto, Ont.**—Permit to reconstruct the munition plant which was damaged by fire has been granted by the city architect to the Toronto Laundry Machine Co. of Dundas Street and Sorauren Avenue. The repairs will cost $15,000.

**Three Rivers, Que.**—Arrangements are under way here, it is understood, for the erection of a $1,000,000 steel plant in this city. The Page Wire Fence Co. of Canada, Walkerville, Ont., which has lately been incorporated with a capital stock of $250,000, is carrying out the undertaking. Montreal capital is said to be largely interested, and the object is to manufacture iron and steel products and ingots.

**Sarnia, Ont.**—A number of factories here have been affected by the order issued by the Ontario Railway Board, cutting off the supply of natural gas for manufacturing purposes. The firms in Sarnia affected by the order are not using the gas for fuel, but for power-generating. The gas engines are in such plants as the Lougheed Machine Co., Sarnia Fence Co., Cleveland-Sarnia Saw-mills Co., Doherty Stove Co., Canadian Printing Co. and others. These firms will have to close unless they can either obtain special permits to use gas or the order is rescinded. The firms cannot secure hydro equipment owing to the conditions prevailing. No gas has been supplied any local firms for fuel since last November. The big plant of the Imperial Oil Co. is not affected. Its gas supply for fuel was cut off with others last November, and since that time oil and coal have been used.

## MUNICIPAL

**North Vancouver, B.C.**—City Council contemplate the erection of a $50,000 filtration plant.

**Picton, Ont.**—The Town Council contemplates installing a pump of 1,000 gal. per min. capacity in its waterworks.

**Strathroy, Ont.**—The Public Utilities Commission is calling for tenders for a pump house. F. R. Smithrin, sec-treasurer.

**Gananoque, Ont.**—Application has been made to the Provincial Legislature for permission to float an issue of $30,000 debentures, $15,000 of which is to pay the general floating debt of the town and $15,000 for extension of water works system.

**Sudbury, Ont.**—The Town Council has petitioned the Provincial Legislature asking for confirmation of certain money by-laws passed by the town. These by-laws are for the issuing of debentures to obtain sums of money to purchase a library site, to get lands for park purposes, for the construction of sewers and water works, for the extension of the present waterworks system and sewers, and for the cost of concrete sidewalks. The money to be raised amounts to about $134,000.

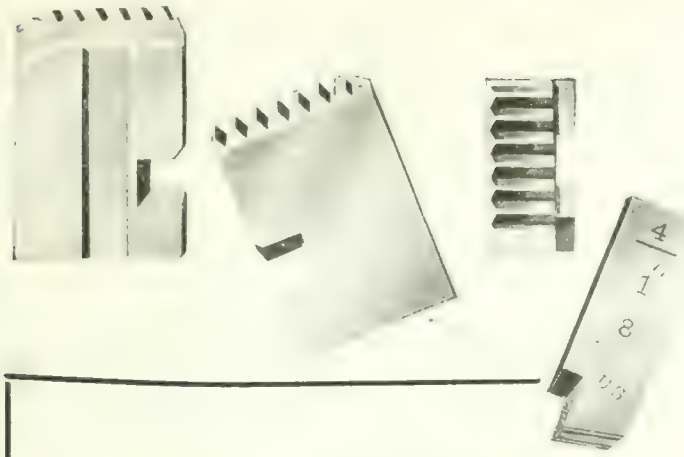
**Chatham, Ont.**—The Ontario Railway and Municipal Board has issued an order permitting the use of natural gas in small factories not using more than 10,000 cub. ft. daily and other plants using coal partly as fuel will also be permitted to use 10,000 cubic feet daily for the purpose of making weldings or other special work. Factories using gas engines, the waterworks, chopping mills and others producing feed will also be permitted to burn the commodity. In addition all factories having war orders such as the sugar factories and flour mills will be allowed to use a maximum of 75,000 cubic feet daily.

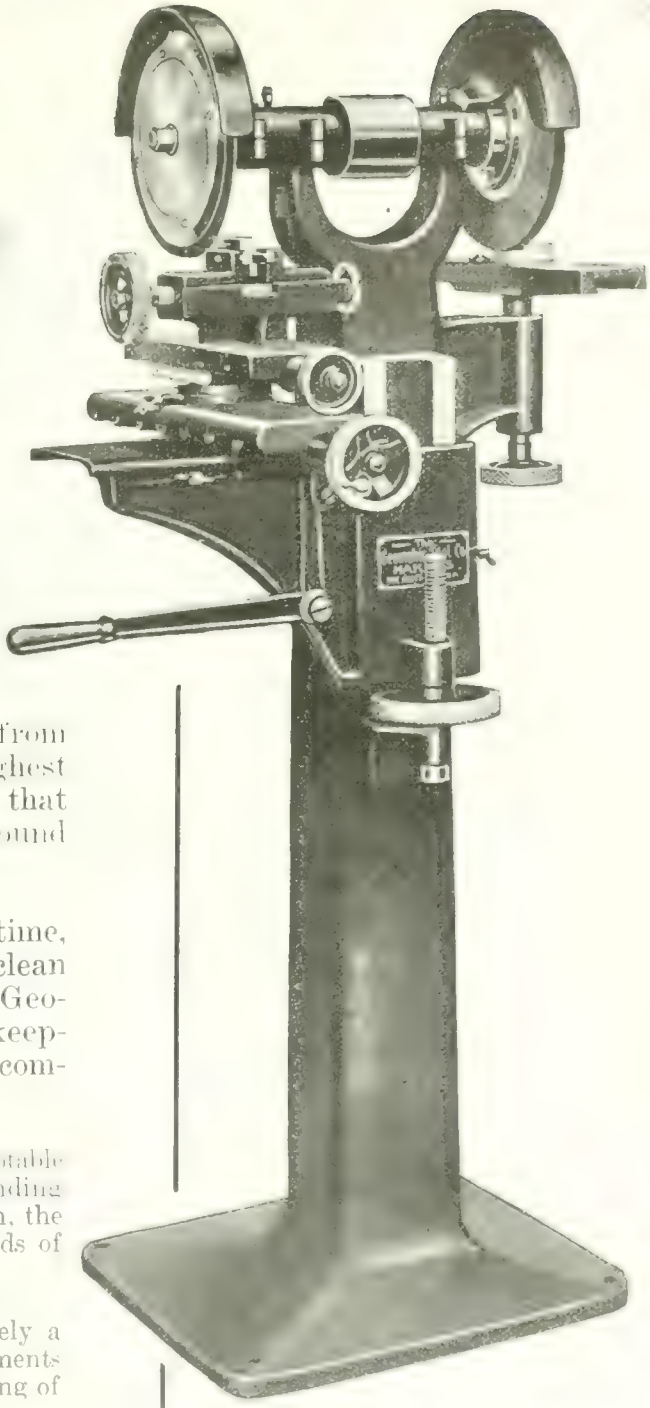
## TENDERS

**Melbourne, Australia.**—Tenders for the following may be addressed to the Director of Navy Contracts, Navy Office, Melbourne: Supply, delivery and erection at Garden Island, of one (1) 200 horsepower prime mover set of either semi-Diesel type or other heavy oil engine direct coupled to 2-65 K.W. 240 volt D.C. electric generating set. All accessories, tank and fittings to be supplied by tenders as per specification. Date of closing June 7, 1918. Tender forms are open for inspection at the Department of Trade and Commerce, Ottawa. File No. 20117.

**Hamilton, Ont.**—Tenders will be received by the Board of Control, up to Monday, March 4, 1918, for supplying the city with the following materials: Castings (ordinary and special), iron pipe, hydrants, valves, extension boxes, hardware, lead pipe, pig lead, road oil, lubricating oil, flux, fuel oil, lumber, gasoline, brass work, including ordinary and special brass castings for the Water Department. Specifications and form of tender for all of the above can be obtained at the office of the City Engineer, Hamilton, Ont.

**Ottawa, Ont.**—Tenders will be received until March 18, 1918, for heating and ventilating equipment required in the reconstruction of the Parliament Buildings. All tenders to be based on the execution, erection and completion; together with the furnishing of all materials, tools, appliances, scaffolding, apparatus and labor required for the installation of the heating and ventilating equipment as called for in the plans and specifications. All information can be obtained at the office of the general contractors, P. Lyall & Sons Construction Co., Ottawa. A set of plans and specifications may be had by depositing an accepted bank





# Sharp Chasers Cut Clean Threads

Accurate, uniform threads result only from dies which are maintained in the highest state of cutting efficiency. This means that chasers must be kept sharp, and ground uniformly.

Even if just touched up from time to time, the chasers respond splendidly, with clean threads. And with this machine—the Geometric Chaser Grinder—the matter of keeping threading tools up to scratch is a comparatively simple matter.

Any make of chaser can be ground on this adaptable machine. The two wheels permit the easy grinding of both milled and tapped chasers. In addition, the plain wheel lends itself readily to various kinds of tool grinding.

Uniform grinding of a set of chasers is purely a mechanical matter through the use of adjustments which can be accurately set to govern the grinding of an entire set of chasers.

***The Catalog describing this machine is a mine of information on chaser grinding. Write for it.***

**THE GEOMETRIC TOOL COMPANY**
**NEW HAVEN CONNECTICUT**

***Canadian Agents:***

Williams & Wilson, Ltd., Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, Winnipeg, St. John, N.B.

may be directed, and be carried out in ... Plans and specifications, and any other information required can be obtained at the ... & Sons Construction Co., Ottawa.

## GENERAL

**London, Ont.**—The ... Co. ... their factory here.

**Port Dover, Ont.**—Last Friday, a fire in the picking department at Penman's woollen mills did considerable damage.

**Fort William, Ont.**—The Ogilvie Flour Mills Co., will erect a warehouse and dock here to cost $80,000. Barnet & Mc... are the contractors.

**Redcliff, Alta.**—A ... concern known as the International Log Bunk & Equipment Co., will establish a plant here for ... apparatus for handling and transporting logs and lumber, etc.

**Quebec, Que.**—The main building of the Industrial Manufacturing Co. at Rimouski, Que., was destroyed by fire Saturday. The firemen saved the outlying buildings of the plant. The damage is estimated at $12,000.

**Winnipeg, Man.**—The Lake of the Woods elevator at Bosenfeld, Man., was totally destroyed by fire which broke out last Monday. Eight thousand bushels of wheat and 1,000 bushels of barley were destroyed. A stock of flour was saved. The total loss will be about $30,-...

## BUILDING

**Ottawa, Ont.**—Plans for expropriation of the land required for the new departmental building to be erected on O'Connor street have been filed. This building will be 200 by 100 feet, and will be in the form of a square with a courtyard in the centre. It will contain 700 rooms. The building will be nine stories high at least, and higher if the city by-laws will permit.

**Ottawa, Ont.**—Hon. Frank B. Carvell, ... the approval of the committee in ... meeting the pressing and growing need for office buildings for the Government in Ottawa. The two wings which will be rushed to completion will contain eighty-two large offices. It is expected to have this ready for occupation by November. The new buildings, as a whole, may not be finished for two years.

## PERSONAL

**R. J. Younge**, general manager of the Export Association of Canada, has been attached to the Canadian War Trade Board at Washington. His duties will ... there will be fully taken care of by the assistant manager and other members of the staff, and there is every reason to believe that the work of the association will not be retarded.

**H. A. Bayfield,** engineer in charge of the building of the Government's big assembling plant at Ogden Point, Victoria, B.C., where all the Imperial Munition Board's ships are to be outfitted, died on February 13. He was formerly Superintendent of Dredges for British Columbia under the Federal Government, and before that was in charge of extensive wharf construction at St. John, N.B., and other Eastern seaports.

**Lieut.-Col. Charles N. Monsarrat,** who has just been elected a director of Canada Foundries and Forgings Co., is one of the best known bridge engineers in Canada. Entering the service of the Canadian Pacific Railway as structural draftsman in the office of the chief engineer in 1889, he was inspector of steel bridges, 1896-97; engineer in charge of designing and erection of important structures in British Columbia and elsewhere, 1897-1901; assistant engineer in Montreal, 1901-03, and engineer of bridges, 1903-11. In 1911 he was appointed chairman and chief engineer of the Quebec Bridge Commission, and to that important work he devoted himself until the completion of the great structure.

## TRADE GOSSIP

**Embargo on Machine Planers.**—An order in Council under date of Feb. 8 has been issued by the Commissioner of Customs prohibiting the exportation, except under license, of machine planers of metal.

**Canadian Crude Oil Advances.**—The sale price of Canadian crude petroleum has advanced 10 cents a barrel, making the price $2.50, with bounty at $3.10½. This is the highest price Canadian crude has reached in over forty years.

**Algoma Steel Corporation Output.**—The output of the Algoma Steel Corporation plant in Sault St. Marie, Ont., for the six months ending Dec. 31, was as follows. The figures are in tons: Magpie ore, 108,824; Helen ore, 44,612; coke, 193,435; pig iron, 147,813; steel ingots, 249,774 tons.

**The Canadian Hoskins Ltd.,** of Walkerville, Ont., manufacturers of electric gas and oil furnaces and pyrometers, are moving their plant from the Walker Building to the Gram building on the Walker road where they will have larger floor space and improved facilities for manufacturing their product.

**The Canadian Locomotive Co.,** Kingston, Ont., has just completed delivery of ten "Mikado" type locomotives for the Grand Trunk, and ten more of these locomotives are on order for use in freight service. Among the new orders placed by the Grand Trunk Railway for motive power is one for 25 switch engines.

**Emergency Fleet Co. Laying 25 Keels a Month.**— George J. Baldwin, chairman of the Board of the American International Shipbuilding Corporation, which has contracts for the construction of ships for the Emergency Fleet Corporation, told the Senate Commerce Committee the company expected to lay fifty keels during February and March.

**Allan Line Discontinues Service From Boston.**—The Allan Line, which for more than 25 years has operated steamships between Boston and Glasgow, is to discontinue its Boston service on May 1. The C.P.R. obtained control of the Allan Line about two years ago, and many of its ships have been requisitioned by the British Admiralty for war service.

**Decreased Output of U.S. Steel Ingots.**—January output of steel ingots in the United States estimated on returns from companies producing eighty-eight per cent. of the country's steel ingots in 1916 was 2,500,400 tons, against 3,106,500 tons, the estimate for December and 3,809,000 tons for October, the month of largest production in 1917. The February rate thus far has been well below that of January. The marked reduction in the pig iron output in the past six weeks points to a shortage in the later months of the year, and this may be more than is now counted on in standard irons since irregular operation of furnaces and poor coke have much increased the percentage of off-grades.

**Dominion Government Buys Ford Tractors.**—The Government has purchased 1,000 Ford tractors at cost. They will be sold to Canadian farmers also at cost, plus freight. Details of freight costs have not yet been worked out, but it is estimated that the average cost to the farmer, including freight, will be about $800. In addition, the Government has secured options on another 1,000 of the Ford tractors. The tractor burns either kerosene or gasoline. It is designed as a two-plough machine. A fuel consumption of 2½ gallons of kerosene per acre is regarded as a fair average. It is claimed for the tractor that it can plough an average of eight acres in ten hours. The ploughing speed is given as 2¾ miles per hour.

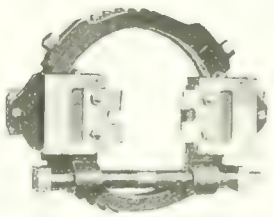
**Big Steel Interests May Merge.**—Reports of a merger between the Dominion Steel Corporation and the Nova Scotia Steel & Coal Co. have been discussed in financial circles for some weeks and more recently have assumed more definite form. According to Mark Workman, president of the Dominion Steel Co., the matter has not been seriously considered as yet although some develop-

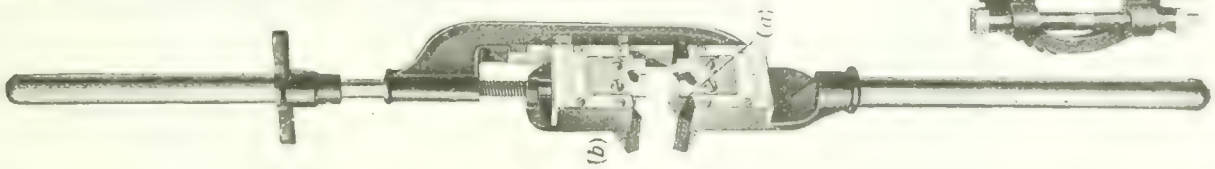
# Beaver Square-End Pipe Cutters

**Adopted** by more than 100,000 users within the last five years because

Beaver Square-End Cutters leave a clean-cut square end. No burr outside to ruin threading dies and no burr inside to be reamed out.

Resharpen the knives on a grindstone after hundreds of cuts and they will make a hundred more as clean and fast as before.





Beaver Square-End Cutters are sturdy, one-piece tools. No feeding necessary—the knives are fed automatically by powerful springs which are compressed when cutter is centered on the pipe. To operate, simply turn "T" handle until "V" jaws grip pipe—then revolve cutter like a die stock.

Do your pipe cutting easier, quicker and better. *Write*

[illegible] was published at Niagara Falls, Ont., last Thurs- [illegible] Niagara River [illegible] control. An additional diversion of 20,000 cubic feet was asked from the [illegible] tion of the upper and lower river diversion of water, at least 575,000 horse-power could be made for American manufacturers without disturbing the existing conditions or lowering the level [illegible]

**Cannot Use Peat for Fuel.**—The fuel famine has aroused interest in the manufacture of peat fuel and has also stimulated the organization of companies to develop the large areas of peat bogs which Canada possesses. It is, therefore, of interests to the general public to know that the Dominion Government, through the Mines Branch of the Department of Mines, thoroughly investigated the manufacture of peat fuel some years ago. The investigation proved that, as the water in peat is what is called the "colloidal" form, it cannot be expelled by pressure. Similarly, processes for expelling the moisture by the application of artificial heat will inevitably fail on account of excessive cost. It is because such methods of manufacture have been stubbornly adhered to in the past that so much money has been lost in attempts to create a peat fuel industry in Canada.

**Sample Fair at Lyons.**—Merchandise intended for the Sample Fair, the third one which is to open at Lyons, France, on March 1st next, will be allowed temporary admission to that country under deposit of duty without special authorization. The period allowed for re-exporting these [illegible] from the [illegible] of the closing of the fair, and no special formalities will be required. Owing to the difficulties of transportation, Canadian and American manufacturers have been unable to send many [illegible] of their wares to Lyons, but they [illegible] their catalogues. At [illegible] Sample Fair, in 1917, more [illegible], of which the United States, through the catalogue exhibit, captured over 50 per cent.

**Quebec Railway to Stimulate Manufacturing.**—At a meeting of the Quebec Railway, Light, Heat & Power Co., plans were discussed in connection with a proposal to advertise the company's [illegible] with a view to inducing Western capital into the Province of Quebec, particularly on the company's lands in and around the City of Quebec, the purpose in view being the furnishing of electric power to the industries backed by the capital induced. The company has water powers at Montmorency Falls, the Natural Steps just above the falls, at the Chaudiere Falls, and on the Jacques Cartier and Ste. Anne rivers. The total amount developed is 48,000 h.p., and there is further power, as yet unharnessed, of 25,000 h.p., with an additional 3,000 when the proposed dam on the Jacques Cartier river is completed. The company is placing before the Government at Ottawa a proposal asking that the company electrify the new Quebec Bridge, and take all trains across by means of electric engines.

# MARINE

**Vancouver, B.C.**—The first of the vessels being constructed at the Lvall shipyard will be named "War Puget" and the second the "War Cariboo."

**St. John's, Nfld.**—The keel of the largest vessel yet to be built in Newfoundland has just been laid at a shipyard at Harbor Grace. The ship will be built of wood, and will be 600 tons deadweight.

**Bridgewater, N.S.**—J. N. Rafuse & Sons, of Bridgewater, have launched a schooner of 113 feet keel, named Industrial, at the Foley shipyard, Salmon river and will immediately start the construction of another vessel off the same model.

**Collingwood, Ont.**—At the annual meeting of the Colingwood Shipbuilding Co., the following officers were elected: President, A. H. Johnson; vice-president, W. G. Smart; managing director, Capt. G. C. Coles and assistant manager G. T. Foulis.

**Vancouver, B.C.**—In addition to getting her hull cleaned and painted, the auxiliary schooner Jessie Norcross, Captain McIntyre, is getting two new tail shafts at the Wallace shipyards. She will leave shortly for Chemainus to load a cargo of lumber for Australia.

**Vancouver, B.C.**—It is understood that several of the dredgers employed by the Dominion Government will be laid up on March 1, until then end of the fiscal year. The vessels affected by the order are as follows: Ajax, King Edward, Mastodon, Mudlark, Victoria and drill plants Nos. 1 and 2, and rock-breakers Nos. 1 and 2.

**Victoria, B.C.**—The auxiliary schooner Beatrice Castle, which was launched at the Cameron-Genoa Shipbuilders' yards about ten weeks ago, being the last of the schooners built for the H. W. Brown interests, has been rechristened the Stasia. The vessel has been granted provisional French registry.

**North Vancouver, B.C.**—The Wallace Shipyard Ltd. will launch the War Power early in March. The War Power is the same size as the War Dog, 4,700 tons deadweight, which the firm put in the water recently. The engines, a triple set of 1,650 i.h.p. are now completed in the yard's machine shop. The boilers, two 15 ft. 6 ins. diameter by 11 ft. 3 ins. long, are being built by the Vulcan Iron Works at their Granville Island plant in Vancouver.

**Montreal, Que.**—The steamship Percesian," commanded by Captain Joseph Bernier, the Arctic explorer, has been sunk, according to a cable received by the Robert Reford Company here. The "Percesian" left Halifax Jan. 1. She was a vessel of 782 tons, the property of the Gaspe & Baie des Chaleurs Steamship Co. She was well known in the local shipping trade, as she was for years engaged in the service between Montreal and Gulf ports. Latterly she had been transferred to overseas service.

**Victoria, B.C.**—Construction of two big tugboats for North Coast service and several scows, all for the Whalen pulp interests, is likely to be the next shipbuilding order awarded to the Foundation Company's yard at Point Hope in the inner harbor. The tugboats will have a length of 128 feet, a breadth of about 26 feet and a depth of 16 feet, so that they will be practically the largest vessels of their kind in these waters, and by a wide margin the biggest and most powerful tugboats ever built in the North-west.

**Vancouver, B.C.**—The wooden steamer War Nootka, launched from the Western Canada Shipyards on January 14, will leave False Creek some time this week. She will be towed to Victoria and berthed at the Ogden Point fitting-out plant of the Imperial Munitions Board to receive her engines and boilers. The spans at Granville street and Kitsilano bridges will therefore be open one morning while the ship passes out. She is the Munitions Board fleet to be launched here. The yard is making good progress on the other three hulls and the number five hull, building on the ways vacated by the War Nootka, is now in frame.

**Vancouver, B.C.**—The wooden steamer *War Nootka*, one of 46 similar standard type vessels contracted for in Canada by the Imperial Munitions Board, has been launched by the Western Canada Shipyards, False Creek, Vancouver. The dimensions of the vessel are as follows: Length between perpendiculars, 250 ft.; length over all, 259 ft.; breadth, extreme, 43½ ft.; breadth, molded, 42½ ft.; depth, molded, 25 feet; depth, over keel, 27 ft.; draft for displacement, 22 ft.; draft over keel, 21 ft.; deadweight on 20 ft. maximum, to Lloyd's summer freeboard, approximately 2,500 tons; deadweight on 20 ft. draft, approximately 2,800 tons. Only the completed hulls are furnished by the

contractors, all other iron work and fittings being supplied by the Munitions Board.

## CONTRACTS

**Three Rivers, Que.**—The St. Maurice Foundry Co. has secured a contract to make cast iron moulds for the Mechanical Engineering Co.

**Winnipeg, Man.**—The following firms have been awarded contracts for supply of cast-iron gate valves, air valves and sluice-gate for the Greater Winnipeg Water District; The Kennedy Valve Mfg. Co., Elmira, N.Y.; Drummond, McCall & Co., Montreal, and the Empire Waterworks Supply Co., Winnipeg.

## REFRIGERATION

**Shelburne, N.S.**—Frank J. Carter, of Dartmouth, it is announced, will build and operate a cold storage warehouse at Shelburne, building and equipment to cost not less than $40,000.

**Toronto, Ont.**—The Provincial Government contemplates purchasing a cold storage building in Toronto for the purpose of saving the fish caught in the summer and fall for use in winter.

**Redonda Island, B.C.**—The Redonda Canning & Cold Storage Co. are having their fish freezing plant equipped with a 12-ton refrigerating machine furnished by the Armstrong Machinery Co., Spokane, Wash.

## WOODWORKING

**Toronto, Ont.**—Fire of unknown origin did $1,000 damage to the C. E. Williams planing mill, St. Alban and St. Nicholas, and $1,000 damage to the contents. The loss is covered by insurance.

## RAILWAYS

**Vancouver, B.C.**—The G.T.P. tug Lorne, recently purchased and refitted, has left for the North to inaugurate the company's transfer barge service out of Prince Rupert.

**Toronto, Ont.**—The Toronto & York Radial car barns on the Metropolitan division, situated on the west side of Yonge street, south of St. Clair avenue, were burned to the ground last week. The damage was roughly estimated by officials at $40,000.

**Toronto, Ont.**—The Toronto, Hamilton and Buffalo Railway is running a line from Dunnville to Port Maitland, on the Grand River, Hon. W. D. McPherson, provincial secretary, announced recently and has a large area of land, between four and five miles long, which will be developed for an industrial site, if present plans carry.

**Ottwa, Ont.**—The Edmonton, Dunvegan and British Columbia Railway Co. will apply to Parliament at the next session for an Act authorizing an extension of the railway to the boundary line between the Provinces of Alberta and British Columbia, a distance of approximately 65 miles.

**Victoria, B.C.**—Legislation that will permit of the completion of the incomplete portion of the Pacific Great Eastern Railway from the end of steel, some 23 miles north of Clinton, to Prince George, and thus finish the line so far as was projected under the contract between the province and the P.G.E. Railway Co., is likely to be introduced at the present session of the Legislature.

## INCORPORATIONS

**The Manitoba Steel & Iron Co.** has been incorporated at Ottawa to purchase and take over the Manitoba Bridge & Iron Works of Winnipeg, Man. The capital of the new concern is $500,000 and the president is Thomas R. Deacon of Winnipeg.

**Monarch Tractors Ltd.**, has been incorporated at Ottawa with a capital of $1,000,000 to manufacture machinery and farm tractors. The head office is at Toronto and the incorporators are E. J. Swift, A. J. Gannon and E. G. Gore, all of Toronto.

**The Ontario Oakoal Co.** has been incorporated at Toronto, with a capital of $25,000, to manufacture a fuel known as oakoal. The head office is at Toronto, and the provisional directors are J. A. Armstrong, J. E. Potts and W. R. Jackson, all of Toronto.

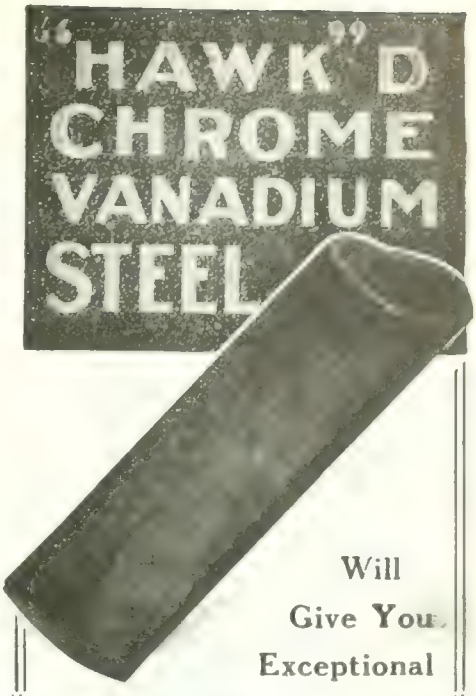
**The Nyanda Pulp & Paper Co.** a corporation incorporated in the United States, has been granted an Ontario provincial license to manufacture pulp and paper products. The capital of the concern shall not be more than $1,000,000. William A. Dowler of Fort William, Ont., is the attorney.

**Metals Chemical Ltd.** has been incorporated at Toronto with a capital of $1,000,000 to manufacture all kinds of chemicals, compounds and to carry on a mining and smelting business at Welland, Ont. The provisional directors are A. W. Holmested, J. L. Ross and W. J. Cluff all of Toronto.

**Green's Economiser Ltd.** has been incorporated at Ottawa with a capital of $50,000 to manufacture all kinds of machinery, plant, mechanical appliances, etc., with head office at Toronto. The incorporators are W. Gilchrist, J. Stewart and H. J. Stuart, all of Toronto.

**Franklin Railway Supply Co. of Canada, Ltd.**, has been incorporated at Ottawa, with a capital of $25,000, to manufacture and deal in railway supplies and equipment. The chief place of business is Montreal, and the incorporators are: J. S. Coffin, jun., of Montreal, also J. S. Coffin and S. G. Allen, of New York.

**The Page Wire Fence Co. of Canada Ltd.** has been incorporated with a capital of $350,000 to carry on the businesses of wire manufacturers, steelmakers, smelters, engineers, etc. The chief place of business is Montreal and the incorporators are A. R. W. Plimsoll, R. Brodeur and A. Clouinard, all of Montreal



Will Give You Exceptional

**Shell Forging Production**

WITHOUT AN EQUAL FOR BOTH FIRST AND SECOND OPERATION PUNCHES.

Comes to you heat-treated and ready for use.

It does not stick to the work.

There are many cases where each punch has turned out over 2,000 shells.

**It means more shells, per machine per day.**

# CATALOGUES

**Recuperative Gas Oven Furnaces** is the title of Bulletin No. 160 issued by Tate-Jones & Co., Inc., furnace engineers, Pittsburgh, Pa. This bulletin is devoted to a complete description of the Tate-Jones recuperative type of furnaces as well as an explanation of their advantages and the economy derived from their use. The bulletin also deals with the advantages of recuperation, construction of the recuperator and measuring the temperature of the work etc., The illustrations show the construction of the furnace and also two types of recuperative furnaces, the views being accompanied by tables giving the principal dimensions for the various sizes.

**Turning Waste Into Profit.**—This is the title of a 28-page booklet, size 8½ x 10¾, recently issued by the Prest-O-Lite Co., Inc., Toronto, dealing with the importance of conservation of steel and iron through oxy-acetylene welding and cutting. This booklet is profusely illustrated with half-tone engravings showing many examples of Prest-O-Lite welding repairs, which have saved money for manufacturers, railroads, mines, machine shops, engineering and industrial plants in almost every line. We have been advised by the Prest-O-Lite Company that a copy of this booklet will be mailed free of charge to anyone interested.

**New Canadian Patents Issued.**—The following is a list of Canadian patents recently issued through the agency of Messrs. Ridout & Maybee, Toronto: Charles Haythorpe, prevention of pitting and corrosion in steam boilers; W. H. Banfield & Sons, central tubes for shrapnel shells; Universal Tool Steel Co., key bolts; Arthur G. L. and Harry C. W. Neighbour, internal combusion engine; Anders B. Reck, sections for sectional boilers; Olof Swanson, plow; James S. Foreman, fittings or supporting combinations for electric lighting and other purposes; Jefferson Glass Co., headlight lens; Herbert Thompson, automatic foot rest shock absorber.

**Venturi Meter.**—Bulletin No. 84, issued by the Builders' Iron Foundry, Providence, R.I., describes the Venturi meter and its application with cold water for gravity mains, filtration plants, pump lines, hydraulic turbines, etc., accompanied by illustrations showing diagrams and installations of standard and special meters. The bulletin also contains a description of the type M register-indicator-recorder with views of charts. The [illegible] contain tables giving principal dimensions and capacity of the various sizes of standard Venturi meter tubes and also gives the directions for installing the venturi tube. Copies of the bulletin may be obtained from the special agents, the Allen General Supplies, Ltd., Toronto.

## MANITOBA STEEL & IRON CO.

THE organization meeting of the Manitoba Steel & Iron Co., Ltd., was held in Winnipeg recently, and the following Board of Directors was elected for the ensuing year:—T. R. Deacon, H. B. Lyall, Sir Augustus Nanton, Geo. F. Galt, G. W. Allan, Sir Douglas Cameron, Chas. Pope, Capt. Wm. Robinson, W. H. Cross. At a subsequent meeting of the directors the officers were elected as follows: T. R. Deacon, president; H. B. Lyall, vice-president; Walter Stuart, secretary.

The company has been incorporated with a Dominion charter, with an authorized capital of $500,000, to take over the merchant end of the business of the Manitoba Bridge & Iron Works, which has grown to considerable dimensions. The new company is strongly financed and will carry on a general merchant business in heavy steel goods, such as structural steel, plates and sheets, bar iron and steel, boiler tubes, rivets, bolts, railway supplies, mining equipment, heavy forging billets and stock for shipbuilding. An entire block of land with suitable warehouse has been secured on Logan Avenue, with railway siding facilities, and business will be commenced on March 1. The business will be carried on along lines similar to the large steel and iron merchant businesses of the United States, contracts for large tonnages being made at one time with the rolling mills. Authority is also given under the charter to build and operate rolling mills and blast furnaces.

The Manitoba Bridge & Iron Works purpose confining their business more to the purely manufacturing side of the business, for which this change will afford them more needed room on their present site. The latter company is also applying for a Dominion charter, with an authorized capital of $1,000,000.

## TRADE ENQUIRIES

THE following trade enquiries have been received by the Department of Trade and Commerce, Ottawa. Further particulars may be obtained on application.

42. **Steel plate.**—A London, England, company is desirous of obtaining steel plates from Canada according to the following specifications: 144 square feet about) of steel stokehold plate, 5-16-inch thick over the checkers, standard sized plate say 6 feet long by 3 feet wide; 3½ tons ⅛-inch mild stele plate; 1½ tons 3-16-inch mild steel plate. The company states that it is inclined to purchase from Canada supplies which in the past have been obtained elsewhere.

43. **Rubber tires for bicycles and automobiles; rubber shoes, rubber hose and rubber belting.**—Wholesale merchants and manufacturers in ths Netherlands would like to correspond and make arrangements with Canadian manufacturers for the 'after-the-war" importation of the articles mentioned. The firms in question are all of the highest standing and could arrange for payments through New York bankers against surrender of bill of lading.

44. **Belting of rubber, balata, cotton and leather.**—Canadian manufacturers interested in the "after-the-war" trade in belting of rubber, balata, cotton and leather are requested to communicate with wholesale merchants and manufacturers in the Netherlands who are interested in the importation of the said

articles. Terms as in the previous inquiry.

45. **Wire nails and straw baling wire.**—Manufacturers and wholesale merchants in Holland would be glad to get in touch, with a view to "after-the-war" trade, with Canadian manufacturers of wire nails and straw baling wire.

46. **Lubricating oils and greases.**—Canadjan manufacturers of lubricating oils and greases, who are interested in the "after-the-war" exportation of such articles, will do well to communicate with wholesale merchants and manufacturers in Holland who are desirous of importing these products.

47. **Graphite.** — Manufacturers and wholesale merchants in the Netherlands wish to get into communication with Canadian manufacturers of graphite with a view to the "after-the-war" importation of the same.

48. **Asbestos.**—Firms in the Netherlands are anxious to prepare for the "after-the-war" importation of Canadian asbestos, and with this view will be glad to get in touch with Canadian exporters of same.

49.—**Calcium Carbide.**—Canadian manufacturers of calcium carbide are asked to communicate with wholesale merchants and manufacturers in the Netherlands who are seeking to make arrangements for "after-the-war" trade in Canadian calcium carbide.

50. **Machinery; labor-saving devices, works and domestic appliances; apparatus, such as railway signals, switches etc., car movers, electric appliances, balers; hardware; anchors and chains; rails, patent sleepers; "chairs," etc.; tramway rails; motor-cars; motor-engines; motor-craft; motor-ploughs.**—A Glasgow firm of importers is anxious to communicate with Canadian manufacturers of the above articles. Writing under date of December 29, 1917, the managing director says: "I have the pleasure to send you enclosed a list of some of the lines which it occurs to me we might be able to handle to advantage on this side, provided suitable arrangements and terms were practicable. My idea is that this business could best be fostered by properly displaying the goods in the ground floor of a public thoroughfare, thus giving the passing public an opportunity not only to see, but also to handle such goods or articles; thus also providing a centre to which likely users and buyers in other districts than Glasgow could be specially invited to come and see and handle the goods, which, of course, is a very great advantage, for any articles not already known, as compared with mail-order business based on mere advertising by people a long way off."

---

THE regimental sergeant-major was on parade, and spotting the recruit, who as usual kept making a hash of things, started on him in a compassionate tone.

"Say, son, if your body was one long fuse, and your brain all gun-powder, and if they burned you, there wouldn't be a big enough explosion to blow your cap off."

# Corrosion of Iron and Steel, and Its Prevention--I.

By Abe Winters

*Perhaps the most pathetic feature of man's existence on this planet is illustrated by the contrast between the enormous metallurgical and manufacturing industries based on iron ore, and the loss of finished metal due to corrosion. Sometimes obscure, sometimes prominently noticeable, the ravages of rust are the most relentless of all handicaps which man lives under, undoing with hitherto unpreventable certainty that which he has done.*

AS the various sulphur compounds act upon silver, covering the surface of it with a film of sulphide of silver which is black, so the oxygen of air acts upon iron, especially when moisture is present. Sulphur which is usually present in the air in some form or other, acts upon a great many metals to some extent when the latter are exposed to the air. Gold is not affected by sulphur or oxygen and is therefore referred to as one of the noble metals.

Sulphur emitted through the pores of the skin will discolor silver ornaments worn by many persons; this fact is particularly noticeable when sulphur is used for medical purposes. Sulphur causes a decided discoloration on silver surfaces but does not necessarily corrode the metal as in the case of oxygen and its effect on iron or steel. Moisture assists the action of oxygen on iron—the surface of the iron being burnt or oxidized and an oxide of iron formed—this we term rust.

John Ruskin is credited with a very beautiful reference to iron as a metal which breathes the air and so gives life to every living thing. If iron could not be oxidized, or rusted we should not exist on the earth. It is the rusted or oxidized iron that gives color to various soils and minerals, it is this rust, which, when dissolved by water forms food for plants and gives the foliage its green color. It is this rust also by which we get iron into the blood and which gives it its red color. With this consideration of iron rust we may be permitted to regard iron as indeed a noble metal. Generally speaking we consider iron rust as a nuisance, it ruins the most magnificent structure of iron or steel as well as the most trivial toy: yet, because iron can rust by action of the air, the metal deserves a place among the noble metals. When the surface of iron rusts, a certain amount of the oxygen of the air is added to the iron. This oxygen has weight and its weight is added to the weight of the iron when the iron is rusty. This oxide of iron, or rust, is easily reduced to powder form and will crumble away under the action of wind or water or any friction against the iron, therefore the iron will lose, not only the oxygen tht it has taken into itself, but also the part of the iron which has combined with e oxygen.

### Relative Corrosion of Iron and Steel

The difference in the rate of corrosion between iron and steel as given by acknowledged authorities varies greatly. The reason for this is plain: the conditions of each reported rate of corrosion, whether the result of laboratory or commercial tests, such as exposure to weather or other corroding influences, not being similar in all respects, are therefore comparable only in a general way.

Experiments conducted by the English Admiralty, various research bodies, international boards of trade and European shipbuilding concerns prove that steel corrodes much more rapidly than iron when exposed to the action of salt water, also that the commoner brands or iron corrode less rapidly than the better grades when exposed to the same influences. No tests of modern rust proofing processes can be considered complete unless the tests include practical application of the salt water action on iron or steel.

Another point to bear in mind is that corrosion tests should not in general be carried out to the limit. The severity with which such tests are carried out should depend upon the stage at which the metals are to be discarded in practice or the condition of the protective coating after reasonable service under usual circumstances.

It cannot be too strongly emphasized that the task of satisfactorily determining the relative corrodibilities of iron and steel is one of immense difficulty in view of the numerous factors involved. The more important factors are as follows:

### Necessity for Representative Samples

(1) Since the metals are made in such a variety of ways and with such varying chemical compositions, it is essential that a very large number of samples be taken. This is where the majority of the investigations are at fault, with the result that the conclusions, although excellent for the field they cover, are not based upon sufficient data to render them of very great practical value.

### Standard of Corrodibility

(2) A method that is adopted very largely at the present time is based upon the loss of weight undergone by the metals when the rust produced by varying media has been removed. In the absence of pitting the results are thoroughly trustworthy and of great valve. But certain kinds of corroding media favor the development of serious pitting, and in these cases the mere determination of total superficial loss in weight may not prove particularly helpful. For example, it is conceivable that a grey iron casting might loose several pounds in weight through uniform superficial corrosion, and yet not be much the worse. On the other hand, a single ounce removed as a result of pitting might be sufficient to perforate the metal and lead to very disastrous consequences. A determination of the depth of the pitting is of the utmost importance.

### Corroding Media

(3) No one type of metal must be expected to resist equally well all kinds of corroding media.

One metal may prove most suitable for resisting neutral corroding agencies, such as tap water or fresh air, whilst another excels in its resistance to the effects of salt water. Two steels may yield amost identical corrosion factors when subjected to various neutral influences, but in 0.5 per cent. sulphuric acid one sample may corrode two and a half times faster than the other sample. It is therefore evident that the nature of the corroding medium must be known before a reliable opinion can be expressed as to the best metal to resist the same.

### Composition of the Metal

(4) Steels offer a very wide range for variation of composition, but for the present we are only concerned with those more common types that are used for such purposes as will bear commercial competition with wrought or cast iron. The main chemical differences are thus confined to variations in the carbon and manganese contents. At the present time the influence exerted by these two eliments, both singly and together, upon the corrodibility of iron has not been thoroughly investigated. Extensive researches on this problem are being carried out but it is too early to discuss the results in detail. It has been observed however that small variations in the manganese content of the metal influence to a very appreciable extent the resistance toward corroding media.

### Physical Condition of the Metal

(5) Iron and steel are, from the nature of their manufacture, particularly liable to segregation and to variation in physical conditions. Modern improvements have tended to minimize the differences between wrought iron and steel, but its doubtful whether the variations in the physical condition of steel will ever be completely corrected.

### Results of Experiment and Experience

More work has been carried out along these lines than the average reader realizes, and a few references to some important cases may prove useful:

Howe and Stroughton in 1908 exposed samples of American iron and steel to various corroding media. Consideration

American railroad.

W. H.

that:

Steel corroded more than iron. 18 cases
corroded equally 9 cases

On the whole therefore there was no

**Conclusion**

The results of many other investigations bear a similar interpretation. We may therefore conclude that, whilst the mean result of examining a large number of samples of iron and steel after exposure to corroding influences indicates that the two metals are practically equally resistant, yet a very wide divergence exists between the different irons and steels in individual cases. This is not necessarily due to any irregularity in the metals themselves but in the majority
is the fact that no one metal can be expected to offer an equal resistance to all types of corroding media.

The question to be considered when contemplating the manufacture of durable iron or steel products is not so much as to whether iron is better than steel or vice versa, but rather—which is the best variety of iron or steel for a specific purpose.

## AERONAUTICS AFTER THE WAR

THE war has forced the pace of aeronautical development to such an extent that we may well wonder what will be the position of artificial flight when the impetus of the present conflict is removed. Aeronautics when the war started was as a young child suddenly caught up out of proper season into the full swing of life. It has been brought to maturity long before its time, and if it now appears a sturdy youth, we cannot help feeling that, like all forced growths, it will sooner or later show signs of its unnatural development. In treating the matter editorially, the *Engineer* states that to-day, no one fails to realise the
ise, what the very circumstances of to-day almost prevent our realising, is the
as applied to peace-time conditions. To-day the aeroplane holds a high position in warfare.

To-morrow, when peace returns, is it to become nothing more important than a carrier of express letters, is it to remain first and foremost nothing more valuable to humanity than a potential weapon of war, or has it the promise of a future in which it will exercise a direct beneficent effect on civil life as far-reaching as its present effect on war? The matter is really one of great practical consequence, for with each day our facilities for building aeroplanes are being increased, more and more interests are being bound up with their production, and the number of those looking directly to aeronautics as a means of livelihood is becoming ever larger.

We can, we think, safely say that as a potential weapon of war the aeroplane will always retain importance, and so far as this aspect is concerned, the future of aeronautics and of aeronautical production is comparatively clear and certain. As such a weapon, the aeroplane will be much on the same level as the gun, the shell, the torpedo, the submarine, and the warship generally. Its development will be subject to similar influences, and its production to similar restrictions.

The prime factor in the matter, however, will not be the actual production of aeroplanes in large numbers, but the provision of means whereby production in large numbers can be speedily undertaken. It would be folly to think that the country's peace-time aeronautical programme can be best carried through on the lines of its naval programme. Ships remain serviceable for a fair number of years after they have been built, so that each year's output represents an addition to those already possessed. Aeroplanes, or at least aeroplanes as we know them to-day, on the other hand, do not "keep." They deteriorate swiftly if used, and only less quickly if not used. Further—although they may in the natural course of things not always remain so ephemeral—the evolution of the aeroplane with all the resources of pre-established industries and accumulated knowledge behind it, seems likely to maintain for a considerable time to come so rapid a pace that the latest design of to-day will be antiquated before the year is out.

Again, the rate of wastage in aeroplanes during war is so heavy that the peace-time provision of large numbers, however great, could never be made to take the place of active production on an intense scale after the outbreak of war. The accumulation of a reserve of aeroplanes during peace is therefore impossible, or, if not impossible, undesirable. The country which the outbreak of war would find best equipped with aeroplanes in being would not necessarily be the best equipped to win the war. The country which had at its immediate command the best and most extensive resources for the production of aeroplanes in large numbers would have the decision in the end. But, as a practical question, is it in any way possible to encourage the creation of resources for aeronautical production without actual production in peace-time?

Is it reasonable to expect that engineering and other firms will be willing to lay down and maintain extensive and expensive plant for aeroplane manufacture, knowing that only in war time would such plant be employed to more than a tenth of its capacity? Even though they were so willing, with the aid, perhaps, of a Government subsidy, the vital question of workpeople would remain. Some scheme might, of course, be adopted whereby the sudden demand for areoplane workers on the outbreak of war could be met by drawing upon certain non-essential industries of a cognate character for labor, which in peace-time had been trained for a period in the aeroplane factories and then returned to its own proper industries. Such a scheme, for what we may call an industrial militia, would, however, involve a degree of Government interference with natural trade conditions that would hardly be tolerated in a time of profound peace, when the emotions and inspirations of the present moment were forgotten. The natural solution of the problem is that the peace-time employment of the aeroplane should be so fostered as to create a demand for aeroplanes for peaceful purposes equal or very nearly so to the numbers required in war time. Then when war came the factories and the workers would be there ready to hand to take up the production of war machines on the scale necessary.

When we look at the matter in this light, we see clearly the evil of the present forced development of aeronautics. It is entirely a one-sided development, a development of the aeroplane as a war machine. Practically nothing has been done since the war started with the aeroplane as a peace-time machine. It is hopeless to suggest that the sporting use of the aeroplane in peace-time will ever supply the demand necessary to keep the required aeroplane factories even partially employed, nor will the Government's peace-time requirements perceptibly ease the situation. Without a strong commercial demand for aeroplanes, it will, we feel convinced, be impossible to keep the factories running on the extensive scale that the situation requires. Where such commercial demand is to come from, we must confess we cannot at present see.

HARDENED work usually requires a larger allowance than unhardened work to enable the grinding machine to take care of the distortion produced in hardening. Bushings which are made with thin walls are especially liable to distortion in the hardening process and require liberal allowance for grinding.

# Inspection and Testing of Spur, Helical and Worm Gears *

By Benjamin F. Waterman

*The author deals with the practical aspects of gear inspection and testing, the methods described being those in use by the Brown & Sharpe Mfg. Co. Close final inspection is of no avail if not preceded by exacting tests between operations and the more exacting the gear requirements, the more exacting must be all the inspections between operations.*

THE inspection of gears requires as much attention as the making. If the requirements are not severe, the inspection need not be; but if the gears must work at high speeds and under severe stresses with quietness an essential factor, the inspection must be strict. In other words, the more exacting the gear requirements, the more exacting must be the inspection, not only the final examination, but also the tests between the various operations, to make sure that the gear is not spoiled, and that other operations will not be performed on a gear that will not pass the final inspection. These inspections are also necessary to insure that one department does not do poor work, with the expectation that some other department will correct the error. The methods given here apply principally to gears of the smaller sizes and are those used by the Brown & Sharpe Mfg. Co.

It is the practice of this company in the case of all gears made to a customer's specifications to first inspect the gear blank. Then after cutting the teeth, the gear is inspected for the running or rolling qualities of the teeth on a hand testing machine, unless the specifications state that the gear must run quietly at some given speed. In this case, the gear is mounted on a power-testing or speeding machine, and run as nearly as possible at the speed at which it will run in practice. When the gears are to be used in the company's machine tools, some of the intermediate inspections, such as the blank inspection, are not necessary. It has been found that any error in the blank that will affect the running of the machine will be discovered at some time before the final inspection of the machine, which is always made under the belt.

It is also the practice of the Brown & Sharpe Mfg. Co. to mark the drawings of gears that will have a speed of over 400 feet per minute with a note to that effect, the note stating simply "Speed 600 feet," or whatever the speed may be. This shows the man responsible for the cutting that he must take the necessary precautions to cut quiet gears and also shows the inspector that he should inspect the gears carefully. It has been found that this practice eliminates misunderstandings as to how carefully the gears should be cut and inspected, and has considerable influence on the time consumed in the cutting operation and the inspection.

### Testing Spur Gears

The method of testing the average spur gears used by the Brown & Sharpe Mfg. Co. is the usual one of mounting the gears on studs at the correct center distance. The most satisfactory way, in most cases, is to have adjustable studs where one fixture or machine will take care of a wide range of center distances; there are several such machines on the market. Where gears are too large for such a machine, a gear-tooth caliper set to chordal figures is a satisfactory way to get the pitch diameter correct. This test consists of callipering the teeth for size and variation; although very large gears may be cut to the correct depth, as the center distance is usually adjustable. In testing the gears used on the company's variable spindle speed and variable feed cases, stud plates are used, where the various gears can be tested at the correct center distance and with each gear it may have to run with. But for general work, standard spur-gear testing machines are used with what is called a spur-gear indicating attachment, which has been found useful for testing the run-out and also the rolling qualities of the gears. In using this attachment the gears are pressed together by springs while a dial indicator presses against a square stud in the slide, so that any tendency of the gears or slide to move away from the mating gear, due either to run-out or poorly shaped teeth is shown on the dial. It has been found that when the indicator pointer vibrates from tooth to tooth not over 0.0001 inch, the gears are usually satisfactory; and when no vibration is shown, the shape of the gear teeth is perfect. Even in the case of spur gears that are hardened and then ground in the hole, it is good policy to see that they are cut true, for then the inspectors need not make allowances for run-out in testing; besides, this practice keeps up the quality, or tone, of the gear-cutting in general.

Transmissions are run off in a test stand of some kind and tested with a light load or without any load. Usually, if a pair of gears or a transmission running dry does not rattle, the gears will run quietly under load.

### Testing the Run-out

A test used in connection with the grinding of the holes in spur gears, for the so-called "run out" in gears is that known as the ball test. The apparatus consists of a pair of centers under a spring-plunger block. A ball on the end of the plunger fits between the teeth of the gears at about the pitch line, and the point of a dial indicator rests on the top of the plunger. The punger block, which is fitted with quite a stiff spring, is used between the indicator and the work to rotate the gear into position while the indicator shows the "run-out," or variation in the pitch line. The final run-out in the gear is tested with this apparatus. The number of spaces the plunger is set into depends on the requirements of the gear.

A gear with a run-out sound, usually causes trouble, no matter how nicely the teeth may be cut or shaped. There can be, and often is, cause for a difference of opinion as to the degree of quietness of a pair of gears, but there is not much chance of this in the case of a run-out, for anyone can detect a run-out sound, and for this reason it is very objectionable.

In the case of cones built up of a number of gears keyed and pressed on a shaft, the inspection for run-out should be made after assembling. Index change-gears and lead change-gears must be cut true, as they are usually meshed closely, and a bad run-out in an index gear might prevent the machine indexing properly.

### Inspection of Bevel Gears

The bevel gears that require the closest inspection are probably the driving bevel gear and pinion for automobiles. It is necessary to hold these closely to figures in the blank, and an effort is made to cut them dead true. It is not good practice to let gears of this type with run-out in the teeth go to the fire, expecting that the grinding department will overcome it. An out-of-round sound is usually fatal to these gears.

After the teeth are cut in driving bevel gears, the soft gears are tested in the hand testing machine with a hardened master gear, to determine the bearing between the teeth and the feel of the gears. They are then tested on a speeding machine with the same master gear and under some load. After they have been hardened and the holes and webs have been ground for the final inspection, they are tested in pairs as they will be shipped, but not in the particular order in which they will be used on the axle. The procedure is as follows: A gear is mounted and several (four or five) pinions are run with it; then the gear is removed and four or five gears are run with these pinions, so that every gear and pinion sent out has been run or tested with one or more pinions or gears. In this way the gears are kept interchangeable as nearly as possible. It can be seen that if the final product were tested with the master gears only, should an error appear in the cutting, the master gears might lend themselves very slowly perhaps to this error and fail to show it; but when the product is run together, an error that might not show with the master gears will appear, and it may be

* A paper read before the Chicago convention of the American Gear Manufacturers' Association.

the inspectors have tested the gears just

amount of run out, the ball-testing fixture is used. This fixture makes it pos-

spindle, and, with the spring plunger block; to bring the space of the gear centrally under the plunger, the dial indi-

The bevel pinion can be tested in this way for run-out by adjusting the plunger block to the suitable angle and setting the pinion on a stud. These run-out tests are not made in the final inspection unless the gears have shown a run-out in the running test. In this case, an effort is made to find the exact amount of the run-out and the possible remedy.

The average bevel gears are tested by hand on a bevel-gear testing machine. Care is taken to have a full length bearing along the teeth; if the bearing falls short of being full, as it may do owing to the need of some working limit, it is expected that it will bear heaviest on the inside or small end, as the bearing will pull in or extend full length with the least wear and the spring of the bearings or shafts.

### Testing Spiral Gears, Helical Gears, and Worm-gears

In testing spiral gears that run at right angles, about the only thing that can be done is to see that the center distance is correct, with some backlash for oil space, and that the surfaces of the teeth are as smooth as possible. Any test of spiral gears other than under actual working conditions is rather unsatisfactory, for they are unreliable to use except where the pressures are light.

This is also true of helical spur gears, as they are made only for high speed, although it may be possible to develop a running test at some speed that will serve to show the defects in the gears, if there are any. The Brown & Sharpe Mfg. Co. has decided that there is no test that can be satisfactorily used in testing helical timing gears by anyone else but the user, and for this reason it has hesitated to cut these gears, as it feels that the user or motor manufacturer should assume the responsibility of cutting them.

Worm-gears, as they are being used to-day, require closer inspection than ever before, as more is expected of them. It was only a short time ago that the worm gear had a poor reputation for service-

of the worm-gear, greater care

Worm-gear cutting equipment, it

the profiles of the hobbing machine are the correct distance apart when the gear is finish-cut. The worm and wheel should be mounted at the correct center distance and in proper alignment to be sure that the bearing between the worm threads and the wheel teeth is correct, a point that increases in importance as the service to which the gears are to be put increases in severity. On large gears, where a testing machine would be out of the question, the worm can be laid in the wheel and measurements taken from a straightedge (laid across the rim of the wheel) to a bar in the hole in the worm or to the worm-shaft. If the measurements taken on one side or end of the worm differ from those taken on the other, it is evident that the shafts are not at right angles with each other. If these gears are mounted in a gear-case in which the shaft bearings have been bored square, the bearing between the teeth will be a cross-corner one, and the amount of this bearing will depend on what the wheels have to do. When the pressures carried by the teeth of worm gears are taken into consideration, it is evident that the bearing should be as full, or broad, as possible.

When testing the average small worm-gear, this company uses bevel-gear testing machine, which is also a worm- and spiral-gear testing machine. But for automobile-truck driving gears, it has fitted up a special machine, where the gears can be run under some pressure. This machine is fitted with a scale and a vernier for reading the center distance.

### Hardening Inspection

Probably no inspection operation depends more for its success on the very operation it professes to inspect than the hardening inspection. When inspecting the machine operations performed on a gear, the mechanical errors can be determined with the measuring tools, and it is possible to feel and hear how smoothly and quietly the gears run. It is therefore possible to pass judgment on them without considering what equipment or methods were used in producing the results obtained. When it comes to testing the gear for the quality of its hardness, however, we find we cannot do more than give it a superficial test, which may mean a great deal if we are sure the hardening was done properly, but which means very little if the hardening was done improperly.

Assuming that the proper treatment for a given gear is known, it is essential that the men in charge of the hardening operation should supervise it closely so that no deviation from the best treatments is made, for the slightest lack of attention produces unsatisfactory or weakened gears which cannot be discovered until they break in service. This satisfactory treatment must be determined by measured breaking tests of gears and an examination of the fracture, to determine not only the depth of case but the condition of the grain of both the core and the case. From a gear having undergone this test, the desired scleroscope and Brinell readings may be found.

This breaking test cannot be carried on indiscriminately, of course, owing to the expense of making test gears, but it is so good a check on the work that it should be done as often as possible or as often as the job will warrant. If gears that have been spoiled are hardened with the good gears and then the teeth are broken, either under a drop or with a hammer, and the fracture is examined, the quality of the hardening may be checked under the best conditions with the least expense.

As a rule, the Brown & Sharpe Mfg Co. also tests every hardened gear with a ball-peen hammer for depth of case and with a file for hardness. The scleroscope and Brinell machines are used as auxiliaries, except where a customer may demand a given reading from either machine when it becomes the decision test.

Besides these tests for hardness, on driving bevel gears, this company tests for flatness on a surface plate and for any disturbance of the web in the direction of the axis of the gear. This test is a hardening-room test, for if it is found that gears are becoming distorted in hardening, it is necessary to change the hardening fixtures.

At times, after all these tests have been made, and probably after any other possible test, there is always the question as to whether the gears will run satisfactorily under actual service conditions. As a result, it is sometimes advisable to have gears tested under these conditions before proceeding at full speed to manufacture. When the gears are satisfactory, it is a good plan to have a pair or set that has been tested out in actual service to hold as master gears, with which the future product can be compared. In closing, it should be said that the amount or severity of the inspection of any gear depends entirely on the purpose for which it is used, although at all times that quality which represents your product should be maintained.

## FUEL RESEARCH IN BRITAIN—II.*

As an illustration of the complicated inquiries which will have to be conducted before an answer can be given to what seems a simple question, the report refers to the suggestion that the cost of producing electric power from coal in this country would be substantially reduced if the coal, instead of being burned directly under the steam boilers, were first subjected to carbonization and gasification processes which in addition to fuel gas would yield valuable by-products. Plausible statements, it is remarked, have been issued showing the enormous savings or profits which would accrue if schemes of this sort were adopted. Unfortunately these estimates have been been made on a very slender foundation of knowledge and experience. On the other hand, those who by experience and practice are best qualified to judge hesitate to prophesy as to what the economic result of a combined carbonization and power-generating scheme would be, but they agree that the in-

*Part I. appeared Jan. 17.

terests at stake are so great that the question ought to be authoritatively answered once for all. But no answer can be accepted which is not founded on the complete working out of the scheme, no important step in the series of operations being omitted or slurred over. This series of operations will start from the mechanical preparation of the coal and its conversion into solid, liquid, and gaseous products by carbonization. It will end with the delivery of a known weight of high pressure steam under the conditions most favorable for power production by turbo-generators. In the proposed scheme of research the investigation of each of the steps involved in the above inquiry is provided for. Three, at least, of these steps involve pioneering work on an industrial scale, and the work may occupy a considerable time. It is possible that the net result of this particular inquiry may be to show that purely as a means of cheapening the cost of electric power the use of carbonization methods has not much to commend it, but will be justified by incidental advantages in particular cases.

### The Experimental Station

The scheme of research outlined in the report cannot be efficiently conducted, it is declared, except in a fuel research station designed and equipped for the purpose, in which operations on an industrial scale can be carried out under proper working conditions. It being realized that the conditions required for such a station could be fulfilled only by a site in the neighborhood of a large gas works, the Director of Fuel Research approached Dr. Charles Carpenter, the chairman of the South Metropolitan Gas Company, some months ago, and subsequently Dr. Carpenter, on behalf of the directors of his company, made the following very generous offer:—

(1) To lease to the Government at a peppercorn rent sufficient land at the East Greenwich Gas Works for the erection of the research station.

(2) To prepare drawings and specifications for the station on lines laid down by the Board and to make contracts for its erection.

(3) To give every facility for the transport of coal and other supplies to the station and to take over at market prices the surplus products, gas, tar, liquor, and coke, resulting from the operations of the station.

The site consists of a strip of level ground, about 250 ft. wide by 700 ft. to 800 ft. long, situated on the main siding which connects the gas works with the South-Eastern Railway and possessing access to an existing road.

### Proposed Equipment

The following description is given of the equipment which will be required for the research work at present in view:—A railway siding will pass through or by the side of the station, and the coal to be used in tests will be received in railway wagons at an unloading platform provided with a sampling floor, a coal breaker and screens, a weighing machine, an elevator, and high-level bunkers. From this the coal will be passed on to the retort house, where ample space will be provided for the erection of the various forms of carbonizing apparatus which are under investigation. Facilities will be provided for quickly carrying out the necessary changes and improvements in the apparatus as the experimental work proceeds. The hot gases will be led from the retort house into the condenser and exhauster house, which will be equipped with condensers, washers, scrubbers, exhausters, compressors, meters, pressure regulators, gauges, pumps, motors, and tanks. For the collection and examination of the gases in bulk gas holders will be provided. The hot coke from the retort house will be elevated to high-level bunkers, from which it can be supplied to gas producers, steam boilers, briquetting plant, or railway wagons. The gas producer house will be provided with one or more gas producers, with heat exchangers, washers, scrubbers, and liquor tanks; the steam boiler house with one or more water-tube boilers of modern type, and with feed water tanks, water and steam meters, pumps, etc.; and the briquetting house with grinding, mixing, and briquetting machines. Tar and oil stills and condensers will be provided for dealing with the liquid products, and the gas furnace house will be equipped for the testing of gas muffles, annealing ovens, and melting furnaces. The station, as planned, will be capable of any extensions required for future researches.

### Scope of Scheme

The scheme of research described is not intended to cover the whole of the territory open for exploration to-day. Still less ought it to be regarded as setting any limits to the exploration of new territories in the future. The root idea of the scheme is that certain fundamental changes in the preparation and use of fuel which have been proposed are of such far-reaching importance that the solution of the technical and economic problems involved ought to take precedence of all other matters. This does not mean that other lines of research will be ignored, but only that the larger issues must be kept well to the front till definite solutions of those technical and economic problems can be given.

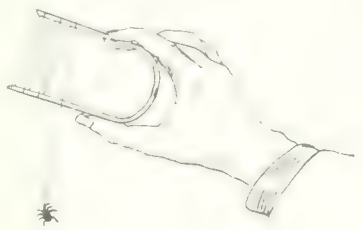
## REPLACING SURVEYOR'S TELESCOPE WEBS

By L. E.

THE spider lines used to mark the optical axis in surveyor's telescopes sometimes break, an accident that renders the instrument useless until the lines are replaced. The job is usually given to an optician to undertake, but the possessor of the instrument may make this repair himself. If the webs of a surveyor's level telescope are to be replaced, proceed by removing the eyepiece and then the focusing-tube, taking out the screws holding the parts that carry the milled head and pinion connected with the rack fixed to the tube.

On withdrawing the collimating screws, the eye-piece and wire plate holder will come apart. The wire plate works in a slide, and to remove it one side of the slide must be taken out. Before proceeding to do this the parts should be examined for dots or similar marks which mark the relative places of the parts when put together. On the side of the eye-piece wire plate next the eyepiece fine marks or lines indicate the places for the spider lines, and to these the new lines are to be applied. With a pen-knife remove the small dots of varnish that have held the old webs in position, but avoid scratching or damaging the marks and the plate will then be ready for the new webs.

Bend a piece of stiff wire to a U form. If a hard steel is used, the temper must be taken out where the bend is to be made by heating in the flame of a spirit lamp or similar means, so that it can be shaped without breaking. The opening



between the prongs should somewhat exceed the width of the wire plate. The fork is for the purpose of straining the spider web so that it can be applied to the wire plate.

A spider that produces geometric webs—the garden spider—as it is sometimes called should be used. On being captured spiders have a habit of drawing their limbs together and feigning death, but if left undisturbed for a short time they resume their activity, and in most cases endeavor to escape by attaching a web to the hand and dropping downwards. When it does this the line suspending the spider must be picked up with the wire fork, and as the web is delivered it should be wrapped on the fork by turning it over, keeping each coil separate as shown in the figure. Of course to ensure even wrapping, the spider shoulld be farther from the fork than illustrated.

When the fork is filled a very small quantity of varnish—shellac dissolved in spirit will answer—is put on the marks that indicate the places on the wire plate for the spider lines, and a length of web as stretched between the prongs is applied. This is a somewhat delicate matter and no specific directions can be given. A good light is necessary and a magnifying glass is very helpful, as is also a small pointed chip of wood to adjust the web in position. When the line is affixed a minute drop of varnish is applied to secure it in place. In the present case there are three lines to be fixed—two vertical lines which are scarcely one-thirtieth of an inch apart and the horizontal line crossing the others. As soon as the varnish is dry enough for handling of the wire plate, the several parts are put together again. Finally the telescope must be adjusted for collimation by the usual methods before the instruments can be used.

# Fundamentals of Apprenticeship: National Interest Grows-.-I

Special Correspondence

*... the principal educational theme ... this country. Employ ... economists, social ... attention with grow ... proposals and the most real and practical experi ... the growing stress of our industrial life.*

... time

Raise the standard of skill in the workman. Improve the tone of industrial morality. Give the greatest number of individuals the opportunity to "live a full and ample life." These are some of the urgent demands of the time.

### Neglect of Old-Time Apprenticeship

Up to within a few years apprenticeship, that is, a type of the old-world guild apprenticeship with its indenture covering a specified time, was little practiced, and the propagandism for industrial education largely ignored it. The beginning of its decline dated from the industrial revolution which took place during the latter part of the eighteenth century, resulting from the introduction of labor-saving machinery and the subdivision of labor.

Before our modern factory system came into vogue most workmen were artisans, masters of their craft; they knew how to perform and could perform the successive stages in the production of a given article. The old labor guilds ... through all stages of development. In ... the laws and customs of Western ... especially required that any per- ... to exercise certain branches ... and trade custom formerly governing the apprentice became largely inoperative and obsolete.

The new industrial system developed the specialist,—he who could do but one thing and must perform this one operation day after day and year after year. It separated by a strong line of demarcation, the skilled worker from the unskilled, and so re-arranged the processes of manufacture that the various stages of production became distinct vocations, the workers in a given department of manufacture being quite ignorant of the work performed in other departments. In consequence of this factory system, and the division and sub-division of processes, the great body of workers of necessity became unskilled machine tenders. To overcome this lack of industrial mastery in the great mass of industrial workers, modern employers resorted to many devices, most of which have centered around the employment of skilled supervisors to plan and direct the work and movements of groups of employees. But all of these devices simply emphasize the fact that machinery without trained intelligence to guide it cannot be fully productive, nor the quality of its product raised to the highest standard.

### Trained Help Necessary

This condition of affairs has not been overlooked by intelligent employers, nor have the serious aspects of a nation containing large bodies of untrained men and women been lost sight of. For some years the growing seriousness of this situation has been receiving the careful thought and study of progressive employers and far-seeing educators, and out of the many hundreds of ideas, plans, and systems which have been discussed and tried out, in whole or in part, certain basic things are making themselves manifest.

It is agreed that no matter how complex the machine, nor how automatic it may be, the worker is the essential factor.

A leading manufacturer expressed the situation in a nutshell, recently, when he said that manufacturers are coming to the conclusion that "the man at the machine is the most important asset, who spells success or failure for any business."

Employers also are now realizing that economical production consists of much more than the mere repetition of machine operations—that it requires a measure of skilled guidance plus the machine operations.

This conclusion has caused a search for a remedy, and out of all the discussions and studies upon this subject there has gradually grown up a demand for a revival of apprenticeship in practically all industries.

As the late Carroll D. Wright well said in his bulletin, "The Apprenticeship System," prepared for the United States Bureau of Education, "It is unwarrantable to argue that the apprenticeship system answers the whole demand for industrial education—but it may do so to a large degree. It is also needless to argue that the industrial schools furnish everything in the way of vocational equipment that can be gained by a thorough apprenticeship system. What is needed is . . . some co-ordination that shall secure all that can be gained from the apprenticeship system and much that can be gained from modern schools for trade and industrial education generally."

The above is the basis of the work attempted by this conference board, and because of the great interest employers are now taking in this subject and the insistent demand that has grown up in all industries for data and information that can be used in applying the apprenticeship principle to industry, the following is offered as a result of the deliberations of this board.

### Personal Interest of Employer

No apprenticeship system nor any scheme of industrial training can be successful without the active interest of the employer. As stated in Bulletin No. 1 of this series, "The employer is the key to the situation." And note that it says "active interest," because the problem of creating an industrial intelligence in the workers who shall man the employers' shops is essentially an employer's problem and cannot be wholly left to pedagogic guidance. There must be a point of live contact between employer and apprentice.

What is an apprentice? The dictionaries give the answer very clearly. Webster says, "One who is bound by indentures to serve a mechanic, or other person, for a certain time, with a view to learning his art, mystery, or occupation, in which his master is bound to instruct him."

Worcester says: "A person bound by indenture for a certain time, to perform services for a master, and receiving in return instruction in his trade or occupation."

The Century Dictionary says: "One who is bound by indenture to serve some par-

ticular individual or company for a specified time, in order to learn some art, trade, profession, manufacture, etc., in which his master or masters become bound to instruct him."

And the Standard Dictionary says: "A person, usually a minor, who serves another in order to learn a trade, art, or profession, especially when bound by indentures for a term of years."

In view of the foregoing it is incumbent upon the employer to exercise a personal interest in his apprentices, and this duty no employer can escape.

Many employers flatter themselves that they are too busy to assume any responsibility for apprentice training, and defer their attention to suit their convenience. On the other hand, employees seek to restrict the number of apprentices in order that they may control the situation. Also many employers have practically no apprentices, depending upon "the market" for their labor supply. They seek the men whom some one else has trained. This method of obtaining a competent worker is akin to stealing him from another employer who, in turn, will do likewise.

### Some Employers' Attitudes

Years ago employers heeded their responsibilities when each journeyman master initiated an apprentice into the trade, but as specialization became more pronounced and individual responsibility became merged into corporate management, apprenticeship training received very slight attention upon the part of employers or corporation officials.

If one will but study the history of juvenile labor he will find that old-time laws laid emphasis on the obligation of the master to the young person employed. It was a two-fold responsibility; the master was answerable for the health and moral development of the lad while in his employment, and for his service to the State and career as an adult since his service and his career depended on his physical, moral, and technical training as a boy.

The interest of the employer in his apprentices will foster and develop a spirit of loyalty and integrity possible in no other way. It will assure the young worker of a "square deal" and prevent favoritism or other unhappy circumstances standing in the way of his advancement. It will do much to dissipate the feeling that the only interest an employer has in his workers is the money gained from their labor. It will develop a wholesome spirit of productive rivalry and build up a type of efficiency which cannot be obtained otherwise.

Of course, it is not to be expected that every employer can personally interview all applicants for apprentice situations in his works, nor that he can personally instruct his apprentices, but he can keep close to the situation by personal supervision of his apprentice department.

Boys are impressionable, and if "the boss" evinces a frequent personal interest in their progress and well-being, they will repay it many times in a quickened interest in their work, in loyalty, in steadfastness, and even in affection.

The Greek philosopher, Epictetus, in his discourse upon citizenship, pointed the way for modern employers when he said, "You will do the greatest good to the State if you shall raise not the roofs of the houses, but the souls of the citizens. For it is better that great souls should dwell in small houses than for mean slaves to lurk in great houses."

### Apprentice Training Under Competent Supervision

Apprenticeship instruction as applied to modern conditions seeks to train for higher efficiency, not simply to train raw recruits to perform the operations now being done by the average workman. To obtain this higher efficiency apprentice instructors must be specially selected for—

(a) Knowledge of the trade, including its historical, theoretical, and practical aspects;
(b) Ability to teach.
(c) Interest in teaching by constant study to add to their knowledge.
(d) Moral character.

Inefficient workmen, who have to deal with inanimate materials, are never retained in a shop. Therefore, how much more important it is that those selected to deal with a material vastly more precious than wood, metal, leather, or stone, namely, the human material, be chosen for their proven capabilities!

It is in the selection of competent teachers or supervisors, that the employers' interest, as previously discussed, should be first manifested. While the small shop employer cannot afford nor be expected to employ a high-salaried apprentice instructor, the large shop employers should seek out the best available teaching talent that will combine thorough knowledge of the industry with pedagogical qualities. It is rare that these combined qualifications can be found in any one individual and consequently, the large shop employer may find it necessary to employ several teachers. Whenever a workman is selected to supervise the apprentice training he should be chosen for his special skill, and, before undertaking to instruct, should receive a course of instruction himself, so that he may know how to correctly classify the theories and practices of his trade in such a way that the young mind may absorb the successive steps of manufacture.

### Cross Ideals

Without [illegible] apprentice is very apt to be exploited to the disadvantage of himself and his employer. For instance, if the boy is left to the care of the average shop foreman it will quickly become evident that the ideals of foreman and apprentice are at cross purposes. The apprentice is intent upon learning the trade. The foreman understands his job to be that of keeping down the cost of producing. Consequently he will look upon the boy either as an unwise burden on his department, or, accepting him as a necessary evil, will compel him to perform certain duties that have no relation to trade instruction. He may even keep the boy constantly employed at some given operation because of a special acquired proficiency instead of advancing him through the various stages.

A similar condition generally results when the boy is turned over to a journeyman worker. In this case the most the boy can hope to acquire is the limited knowledge possessed by the journeyman, and the latter is apt to do one of two things: either use the boy as a helper without regard to progressive instruction, or deliberately prevent the acquirement of knowledge because of ignorance or prejudice.

Employers will find that it will be quite necessary to educate their foremen to give apprenticeship its rightful place in the plant, as well as to impress upon journeymen workers that the boys under training are to receive special consideration.

Large employers of labor can prevent exploitation of the boy by the employment of supervisors, who have special competency for this work, and by the establishment of [illegible] successfully in a number of shops, namely [illegible] the jurisdiction of the supervisor rather than the foreman, and the shop work selected for the apprentice must be of an educative nature, an industrial curriculum over which the supervisor has full control.

In small shops the employer himself can and should supervise the work and study of his apprentices, directing fore[illegible] teach and how the instruction is to be given.

## ENGINEERS FORM NEW ORGANIZATION.

THE Kootenay branch of the Engineering and Technical Institute of British Columbia was formed at a recent meeting in Nelson, B.C., the headquarters of the branch.

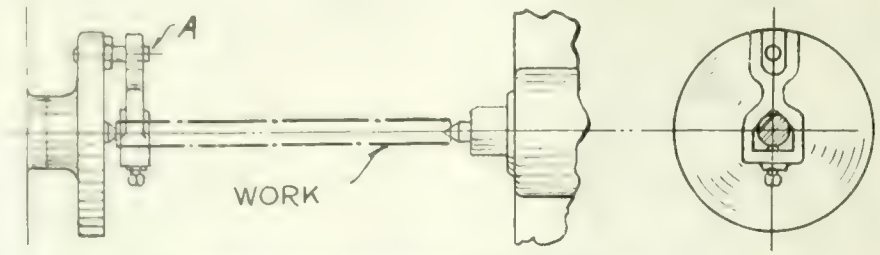
The institute, which is applying to the legislature at the forthcoming session for a charter, will be an organization composed of civil and mining engineers, architects and members of the allied professions.

The following provisional officers were appointed: Wm. Cunliffe, chairman; A. E. Pickford, secretary-treasurer and A. E. Thompson, assistant secretary-treasurer.

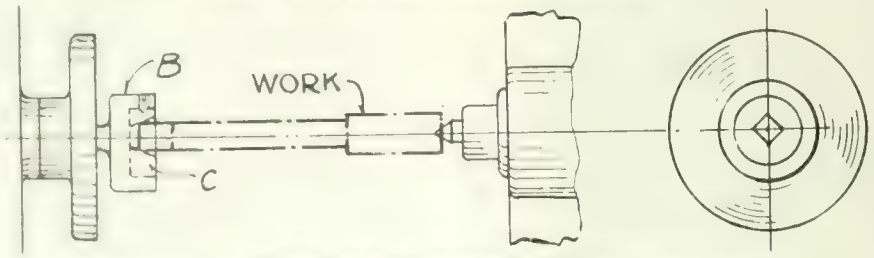
**British Trade Inquiry.**—Particulars concerning the following inquiry may be obtained from the British Trade Commissioner in Canada, 363 Beaver Hall Square, Montreal. A London, England, manufacturer of glaziers' diamonds, diamond turning tools, glaziers' lead vises, etc., desires to get in touch with Canadian buyers.

# PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience



Method of driving with dog and pin in face plate.



Squared center in headstock spindle.

FIG. TWO TYPES OF DRIVES FOR WORK BETWEEN CENTERS.

[illegible] evidence of its convenience on the lathe for holding and driving work, some of which are of standard [illegible] chuck and two types of lathe need no extensive description as their place as part of a lathe equipment is well known and fully taken advantage of, even to the exclusion of some tools which might be more profitably used in specific [illegible] by means of a pin or screw A in the face plate. The purpose of this dog is obvious as the method of handling it is similar to that in use for the various types of dogs. In the lower view of Fig 2 a method for driving work which has a square on the end of it is shown, this consists of a center B held in the head-stock square bush C in it, made in various sizes to suit different diameters of work. These bushings with the square hole in them are beveled, the front end being larger than the back. In using this center the squared end of the work is simply pushed into it and held in place by the tail-stock center in the other end; working in the usual manner, light operations may be performed.

In operation this method of driving work is quite fast where it can be applied satisfactorily. The driving centers may be made in other shapes besides the square, such as hexagon, rectangular, etc. A center which answers the same purpose as that described above as used for driving work where the end is not shaped is illustrated in Fig. 3. The difference between this center and the square center consists of corrugations in the beveled hole at A, these corrugations acting in the nature of a number of teeth which grip the work when it is forced in by the tailstock center. In putting work into this holder it is not necessary to stop the machine, and such operations as chamfering and necking are thus rapidly performed.

Another method of driving from a squared end is shown in the lower view of Fig. 3. This is a more accurate method of holding the work, inasmuch as the same is held between centers, the driving, in this case, is done by a bent plate B which has a slot cut in the end to receive the work. This plate is held on the face plate of the lathe by means of a screw C.

In instances where there is no square on the work the driving may be done as in Fig. 4 upper view, provided there is no objection to slightly marring the work. This device consists of a lever A which has teeth cut in the gripping surface of the same at B, this gripping surface is machiner eccentric with the center hole C on which it pivots, the radius at Y being about 1/16 inch less than the radius at X. With this arrangement the lever is forced into the work when a cut is taken, thereby driving same. In some instances the teeth on these levers are omitted and the wedging of the eccentric surface is sufficient to drive the work.

In driving work by this method considerable strain is placed upon the headstock center and if an attempt is made to take a heavy cut the center hole is quite apt to be forced out of round there-by making poor work. When taking heavy cuts upon a lathe considerable difficulty is often encountered by the dog slipping, or in other words one screw is not enough to take the whole strain of the cut. In such cases two dogs can be used as shown in the lower view of Fig 4 to good advantage and it will be found that this arrangement is sufficiently powerful to drive under almost any cut. In this illustration the tail of the dog D lays against the tail of the dog E, this dog in turn being driven by the face plate in the usual manner. What actually happens in this instance is that the strain of the cut is divided between the two dog screws.

[illegible] TOOLS

Having reviewed in general various dog methods of driving which are doubtless familiar to many although probably suggestive to some, reference is made to Fig. 5, which shows a group of lathe face plates. The two upper face plates shown are of the plain slotted and plain drilled type which screw on the spindle nose. In the center of this illustration at the left is shown a chuck or face plate; this is held in the lathe spindle and has different diameters bored in it, thus work corresponding to any one of these diameters may be held. These chucks have a tapered shank on them and are drawn back into the spindle nose which causes them to collapse and grip the work, three slots being cut for collapsing purposes.

The illustration to the right of this shows a face plate which has two vee grooves cut transversely at right angles across its face; this is a convenient face-plate for gripping round work and drilling cross holes through the diameter. In the lower left hand corner of this illustration a face plate provided with four clamps for holding work is shown. On some of these face plates it will be noticed that lines are cut around the face plate and these are convenient for locating work approximately.

A description of work holding devices which did not include the chuck shown in the upper view of Fig 6 would be far from complete. This is a small drill chuck and these chucks are made in quite a number of sizes and varieties by various makers. In the lower view of Fig. 6 an arbor is shown, this arbor being of the split bushing type, a nut A being used to expand it by forcing the bushing over a tapered shank. For removing the work from this arbor the nut B is used to push the split bushing back.

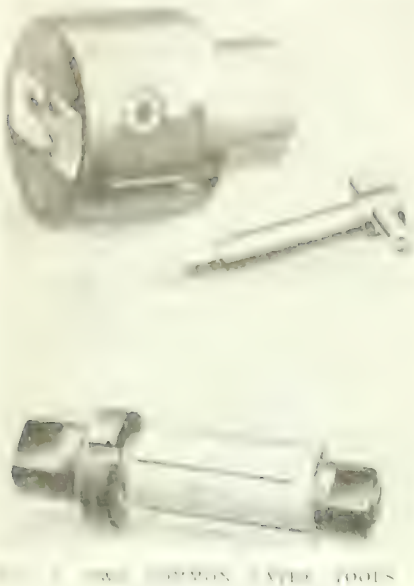
## AN IMPROVED STOCK RECORD FORM

By D. O. Barrett.

THE accompanying stock record had been worked out after using various other standard forms with varying success. It may be used either as a card record or in book form without impairing its usefulness in any way, though in general the card record is probably the most convenient. It will be noticed that there are three main columns—RAW STOCK, STOCK IN WORKS AND FINISHED STOCK. The use of this record does away with the necessity of employing any form of tickler to care for orders, either for material or for work in process, as this information is all self-contained and entered the same as if other forms were used.

Following up the entries, we see that 16 rough castings were ordered 9-16 on order No. 138. All orders, whether for castings made directly in the plant or for outside purchased material, are made out in triplicate, the third copy being sent to the stock room or to the cost clerk, provided the records are kept directly in the stock room. He enters the information on the form and returns the copy to the office, as this is the only information which interests him, and enables him to



by col. 8. On 9-23, 3 of the finished castings were received in the stock room, giving a "Total" of 3 (col. 14). Two of these were issued 9-23 on order A59, leaving a "Total on Hand" of finished stock of 1. Eleven rough castings were received 9-21, completing the orders, as shown by col. 6, and giving a total of 12 "On Hand," col. 7. Col. 8, line b, is left blank, and col. 7 indicates the amount of stock. When material is issued to the shop the amount is subtracted from col. 7 and entered in col. 8 on the same line, so that it is easy to determine which represents the "Total."

Ten more castings were ordered on order No. 157, dated 9-25, these being received on 9-28, completing the order and giving a total of 22 rough castings "On Hand." Order No. 9238, dated 9-30, sent 20 of these into the works, leaving 2 castings "On Hand," as shown by col 8. These finished castings were received 9-30, and with the 1 "On Hand," as shown by col. 18, gives a "Total" of 21 (col. 14), 14 of these being issued on order No. 378, dated 10-2, leaving 7 "On Hand."

The remaining 7 castings were sent into the works on 10-5, order No. 9296, leaving the raw stock entirely depleted with 2 and 9. The finished pieces were received 10-6 and with the 7 "On Hand" gives a "Total" of 9 (col. 14). The total of finished stock is indicated either by Col. 14 or col. 18, depending on whether the latter column is filled.

It will be noticed that this form allows the use of every line entirely across, and these would be entirely filled were the entire stock handled on each order. The next order entry will now be made on line (e). The card is, of course, made longer than the one shown to suit the conditions. Practically all the information regarding any one piece is contained on the form, and its use greatly facilitates the taking of inventory, as it is unnecessary to look up several records to get the requisite information. The same form is used both for purchased and for manufactured material, though for the former some of the columns are not used.

## TIGHTENING A LOOSE HANDLE

J. E. McCormack.

A type of tool handle made of wood with a socketed clamping nut proved to be a difficult thing to tighten up on occasions when it became loose. There was no opportunity for using a wrench or screw driver on the nut and the handle would not turn by hand. The difficulty was overcome by wrapping a piece of leather around the wool, and then applying a pipe wrench to the leather protected part which on the removal of the leather showed no scratches or dinges.

As tools of this and similar classes are common in machine shops, this may be of interest to others and the idea can be applied to any wooden object of similar size and nature.

## A CHART FOR FINDING THE LENGTH OF COILED PIPE, ETC.

By N. G. Near.

WITH the aid of the acompanying chart it is a simple matter to determine the length of a coil of rope, the length of a pipe so familiar to the plumber, the length fo a coil of rope, the length of a coil of wire, or a coil of almost anything as a matter of fact. This chart, however, was made primarily for pipe. The size limits of this chart, it will be noted, range from 1 to 30 inches in diameter (column A) and from one to 60 turns (column C). This limits the charts to a bit over 400 feet.

To use the chart, measure the "average" diameter of the coils as indicated by the sketch on the chart itself. That is, measure from the "mid-point" of one side to the mid-point of the other side in inches. Then count the number of coils. Then connect the diameter (column A) with the number of turns (column C) and the intersection with column B immediately gives the total length in feet.

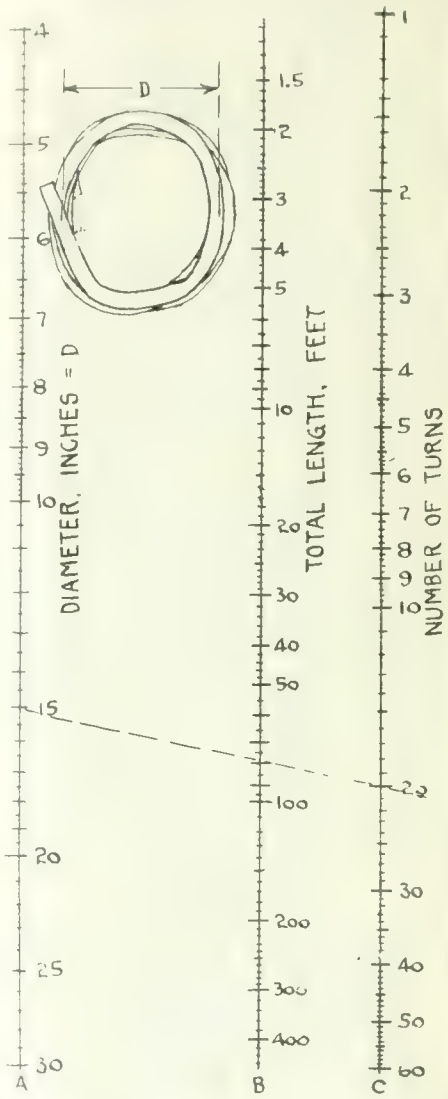

CHART FOR DETERMINING THE LENGTH OF COILED PIPE, ETC.

For example. What is the approximate length in feet where the diameter is 15 inches and the number of turns is 20?

Connect the 15 (column A) with the 20 (column C), as indicated by means of the dotted line drawn across the chart and the intersection with column B immediately shows the length of the coil of lead pipe or whatever else it might be as very close to 79 feet.

It is evident that it is much quicker to use this chart than to unroll the pipe and measure it, or even to compute it, knowing that to compute one must divide the

diameter in inches by 12 and multiply by 3.1416 and then by the number of turns in arriving at the result. Besides, this method is just as accurate anyway because of the judgment that must be used in measuring the diameter.

This method is much quicker and easier than to unroll a long coil and measure it with infinite care and then roll it up again. The method is not "absolutely accurate" but for most rough purposes it will do very well indeed. If it is desired to determine the "exact" length within an inch or even a foot (provided the coils are large) there is no surer method than unrolling and measuring in the longhand way. But if the answer is wanted only approximately, why do it the hard way?

## HEAT TREATMENT OF SHELLS

By G. C. White

THE heat treatment of shells has developed many new types of furnaces and methods of handling. The quenching bath has proved to be not the least important as various contrivances have been used to facilitate handling and cooling. Some of these requiring compressed air have proven very costly.

A good method for keeping the oil cool with such large bodies of metal being quenched is to partly surround the oil quenching tank with water, about 8 inches around the sides and bottom. This water is changed very gradually by running the fresh water in the bottom and having an overflow pipe on the surface.

In the bottom of the water tank are coils through which hot oil is pumped from the surface of the oil tank. These coils containing the oil are connected to an elevated tank which contains a small sized mesh diaphram which splits up the body of oil as it is allowed to fall. These drops of oil cool and fall into another tank from which the cooled oil is pumped into the bottom of the quenching tank proper.

This arrangement of piping conforms in detail to the requirements of the insurance companies except that the elevated tank should not be near the roof.

The quenching tank should have a metal elevated hood which is held above the tank by a rope. If the tank should become overheated and flash the rope would burn through and allow the hood to fall, smothering the fire.

The speed with which cooling is accomplished is as we all know very important and on it depends whether the steel breaks up into the constituents possessing extreme, intermediate or only slight hardness.

Results of tests show that for each increase of 50 degs. F. over 100 degs. F. oil temperature the cooling of the steel is retarded 5 seconds. These results are comparative for the same sized test piece made in the same sized quenching bath.

The most extreme hardness is very seldom attained in commercial practice due to the time taken to quench and the irregularities of shape would set up hardening strains of too severe a nature.

## NOSE BEVEL GRINDER FOR SHELLS

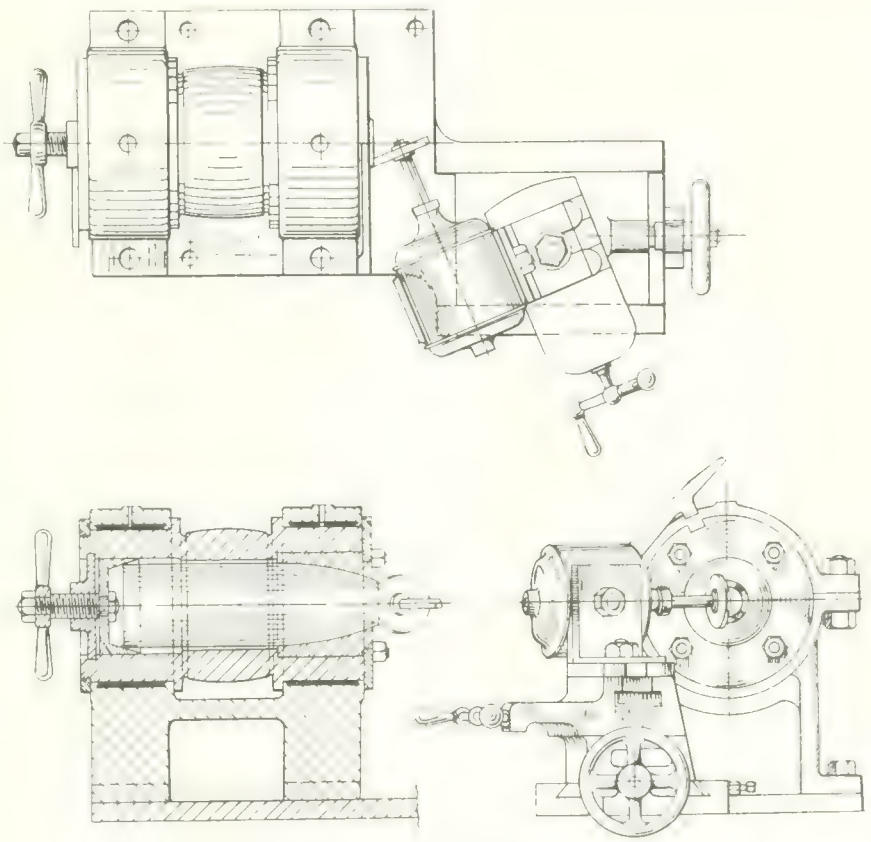
By M. C. Hemeon

MANUFACTURERS of 4.5 in. shells have experienced some difficulty in correctly machining the nose-bevel or seat angle of these shells, with respect to quality of finish and perfect alignment of seat angle with the center line of the 2 in. tapped fuse-holes. The method, generally used has been to finish with a rose reamer revolved by hand on a stud which screws into the nose of the shell, and is there expanded to insure rigidity.

This arrangement has not been entirely satisfactory and the accompanying sketch illustrates a simple power driven machine which has overcome the difficulties of alignment and finish. The shell chuck consists of a cast iron sleeve with a bearing on each end and a pulley in the center. The sleeve is bored at one end to take a hardened steel bushing, the bore of which is the shape of the shell nose. The opposite end of the sleeve is bored to take a centering cup, which is adjusted and locked by a cross-handle and screw tapped into a flange nut. The sleeve revolves in cast iron babbit lined boxes.

A [illegible] in. x ½ in. face emery wheel mounted on the spindle of a small electric grinder, made fast to a rest. As the shell revolves, this wheel is run over the face of the seat. An adjustment in line with the shells compensates for the wear of the wheel.

Firms using thread millers and milling the threads after finish turning will find this tool very satisfactory.



DEVICE FOR GRINDING NOSE THREAD [illegible] SHELLS

## WOMEN AS SMALL ARMS INSPECTORS.

THE U. S. [illegible] women to qualify [illegible] small arms, according to announcement made by the United States Civil Service Commission. The examination which the commission is receiving applications to secure persons equipped to serve as inspectors and assistant inspectors of small arms, in the plants filling contracts for the Army, is the first of its kind opened to women, it is stated.

## U. S. COAL CONTROL

ORDERS under which the United States Fuel Administration will obtain absolute control of the coal and coke output of the nation as soon as existing contracts run out were made public last Thursday at Washington. It is provided that no new contract shall be for a period longer than one year, that all contracts may be cancelled at any time by the Fuel Administration, and that all coal thus sold under contract shall always be subject to requisition by the Government.

Contracts for coal shipments involving what is known as a cross-haul are absolutely forbidden. Under this ruling industries in various sections of the country must obtain their supply of coal and coke from the fields nearest to their plants. This rule will not apply to gas coal and coal used for by-product purposes.

The new orders are the most important which have been issued by the Fuel Administration for many weeks.

# LET THE DANGER TO CANADIANS AT THE FRONT COME FROM THE GERMANS

## What Happens When a Premature Explosion Takes Place at the Front

## Campaign Being Put on Now by the Munitions Board to Arouse Workers

"Well, there's what happened to me." [illegible] a bit more lucky than many another chap who runs into the same thing. You see it was this way," he went on. "I was in charge of a couple of guns not far from the road. On the other side of that road were four other guns lobbing shells over for a throw of about four thousand yards. The one that got me didn't get over four hundred yards [illegible]

CANADIAN MACHINERY, to whom the officer in question was speaking, asked if the men [illegible] sible to do away with premature explosions by rigid care and inspection at

"No, I wouldn't care to go that far," was the reply, "we realize that there is the element of chance in war, and it simply can't be eliminated in its entirety. At the same time the people who are working in shell plants ought to have brought before them every day and every hour if possible the serious side of the business in which they are engaged. Look at it this way. When a gun crew at the front gets the word to go into action, it means action in every sense of the word. The men grab the shells from the racks, they jam them into the guns, and they fire. Never for one minute do they think that the shell is imperfect. The fact that it has been, in nearly every case, made in Canada, is enough for them. Why in many cases, they find marks on the boxes showing that the shells have been made in shops in cities from which the artillery men have themselves come. Now, get this, the gunners go into action in good faith. It's up to the people at home to [illegible] fair."

[illegible] Mean

"It depends on the location, and the [illegible] pits and the enemy lines than they do to the gunners themselves. But get my big point again," said the officer in conclusion, "remember, the [illegible] at the front expect a certain element of danger, but get the munition [illegible] at home to see to it that they reduce it to the minimum. **Let's have all the danger coming to us from the German lines, where we are looking for it.**"

### A Campaign of Caution

Fear [illegible] and blood are greater than contracts and profits is really at the bottom of the campaign that is now being put on under the auspices of the Dominion Munitions Board. It is really backing up the views expressed in the interview above. The appeal is not limited to the inspectors, nor the manufacturers, nor the workers. It is big enough and compelling enough to take in and include pointedly and directly every individual who in any way touches the production in any phase.

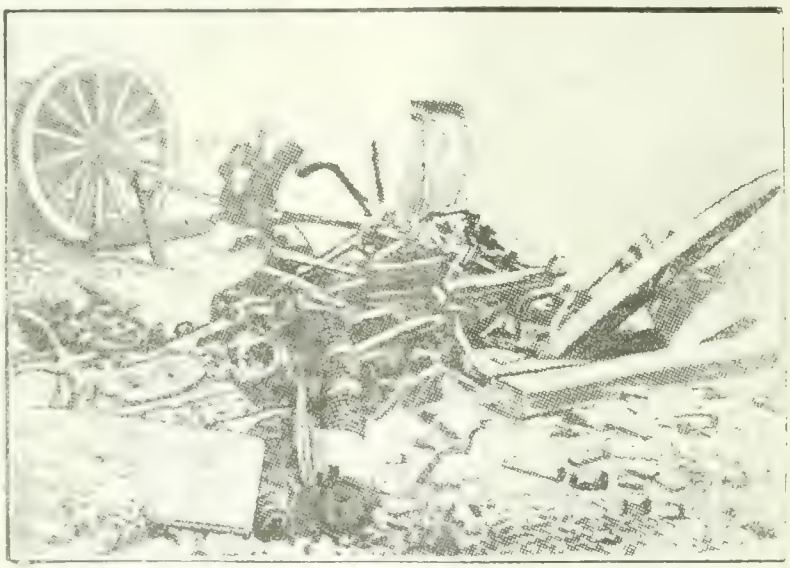
### The View of the Board

CANADIAN MACHINERY has in its possession the views of a very prominent member of the Munitions Board. This member has the right slant to his view. He insists that the man at the front who has to use the shell, and who is in danger from a faulty product, is the chap who must continually be kept on the mental horizon of every person engaged in the production of munitions.

The matter of inspection is one that has raised a very great deal of controversy. It will probably continue to do so. The position, in short is this. The manufacturers say "This product in which the process of machining brings out a defect and causes a rejection was sent on to us from the rolling mills. It was not originated in our plant. We have no control over it in any way. Why, then, should we be called upon to absorb or bear the loss incurred in the employment of the labor that is necessary to bring these defects to the surface?" And on the face of it it looks as though they were able to make out a pretty fair case.

### At the Other End

Then the men in charge of the forge plants where the first operation takes place assume this attitude: "We took the billets and turned out the rough shell. The government have inspectors at our plant, and they pass on every piece of work that goes through. So if the product is not good when it comes to be machined, we don't see how you can turn it back on us." And here, again, it must be admitted that the forge men have a fairly respectable looking alibi when it comes to the matter of placing the responsibility.



GUNS ONLY FIRE ONE DEFECTIVE SHELL

### The Middle Course

The Munitions Board are apparently willing to meet the manufacturers and the steel men on a fair basis in regard to this work. In fact it is known that only a few days ago claims were allowed by which the Munitions Board absorbed a large amount of losses incurred in this way. One Toronto firm, now working on the 4.5 shell, explained to this paper the basis on which their losses were adjusted. It is all based on the amount of labor that the manufacturers have put on the shell before it reaches the point where it is called defective and rejected on that account. For instance, it would not take nearly as much labor cost were the defect found in the first or second operation in the plant as if the shell

had gone well on toward the finished product before the weakness were found in it. This basis will probably be the one on which a very equitable solution to the whole vexed problem can be worked out.

### No "Average Goodness"

"Here's something," remarked a high official to CANADIAN MACHINERY, "that people are apt to overlook in the making of shells. There is no such thing as an average. Each shell, on its own merit, is either good or bad. That hardly applies to any other business with the same force. You can turn out 999 shells and make them all good, and the one that would raise the number to the thousand mark might be bad. The perfection of the 999 would not help that last one—not a bit. It would be bad. You can take a man, and throw all his qualities, good, bad and indifferent, in a heap, and after sizing up the pile conclude that he's not a half bad chap, taking him all in all. You can't do that in the shell business," concluded the official. "Each shell is either good or bad on its own merits."

### Looking to the Future

The man who could tell you how long the shell business will last in Canada could probably tell you in the next breath when the war was going to end. Some of the makers, especially those working on the 4.5 and 6 inch shell, are beginning to see the end of their business, and in some cases they have not yet had a sufficient turnover to justify their capital investment. Although it has not been definitely announced, this paper has it on good authority that Canadian shell-makers will probably have a chance to work on orders for the American government in the near future. At least they are being urged to adopt in a sense the policy of watchful waiting in their business. One Toronto concern, with a Buffalo branch, is already handling a certain amount of the work here. In many other cases, British orders are being renewed regularly.

### A Great Service

The official to whom CANADIAN MACHINERY was speaking was enthusiastic over the accomplishments of the Canadian manufacturers since they went into the manufacture of shells. He urged that the whole field be surveyed from the start, and the run-down conditions of Canadian plants at the start of the war be considered.

"Look at the thing fairly," he said. "We have made millions upon millions of shells, billions of parts; we have established a record in the making of shell boxes—we are doing all sorts of things we never did before. We are bringing untrained men and women into the shops and training them to the stage where they can, in many cases, work accurately to the thousandth part of an inch. Records show that on the whole we are putting more conscience into our work than the American mills. The great overwhelming body of the work has been well done. The accomplishment of the Canadian manufacturers in meeting the demand for shells is nothing short of an industrial romance."

# Industrial World Must Realize Waste is Greatest Enemy

By Wm. C. Redfield, U. S. Secretary of Commerce

*United States offered some up-to-date lessons. Can be something of advantage from the Germans. Go into the industrial contest the same as through prepared for war*

AMERICAN manufacturers will have a vital part to play in the future of the country. This part will be more important than it has ever been before.

It will not be merely that of securing their own prosperity but of assuring the prosperity of the country as well in a sense that has never been true before.

Our power to grant credits at home and abroad depends on maintaining our gold reserve, which is the basis for those credits. If that gold reserve is greatly diminished there will be less credit available at home. We shall not be able to look abroad as before the war for a supply of credit. We must furnish it ourselves. I know of but four ways to protect the reserve on which these credits depend. These are loans abroad, investments abroad, sales abroad or services abroad. Our ability to keep a supply of credits sufficient for our domestic business depends upon these four things.

[illegible] American manufacturer must fight in protecting our domestic credits by selling goods abroad are chiefly domestic. Four are of especial importance. First, I should put the failure to apply science to industry. Germany did this more than any one and prospered thereby. The use of science in industry has greatly grown during the past three years. It must grow more. Unless we are as competent to apply science to trade as others we must not expect to lead them successfully. We shall not deserve to win in the future industrial field unless we apply knowledge to industry as well as others.

A second enemy is the lack of industrial training for workers. In German factories before the war men of science led forces of trained workers. We have made a great start in this direction through the law providing Federal aid to vocational education, of which every State in the Union has now taken advantage. This act will, in my judgment, be found to be more helpful to American industry in coming years than many things that have been more visible to the public eye. When we have trained minds leading trained workers two great steps forward will have been taken in American industry.

A third enemy is ignorance of costs. This has prevailed to an appalling extent. It must go, and with it must go the rule of thumb and all guess-work in industry if we are to deserve the place we hope to gain and keep. We cannot compete with men who know what every process costs them if we have not like knowledge ourselves.

A fourth enemy—and a bad one—is waste. We have thrown away fortunes in the wastes of industry. Take, for a simple illustration, the whaling industry. This is one of our oldest, carried on for over a century with what we have been pleased to call great success. Now we know that most of the values of the whale have been wasted. Fine leather is now made from the whale's skin, from the intestines, the stomach and from other parts. Several tons of good meat are now taken from each whale and find regular consumption. These and similar things may soon come to be the chief products of an industry which for long decades has thrown them away.

If we will waste we must expect to want. Waste in one or another form has been, and, though greatly reduced, still remains one of the great characteristics of American industry and life. We have learned much and are feeding nations from what we now save, but there is much yet to learn.

There are many fine examples in our industry of science applied to business, of trained workers, of clear knowledge, of watchful saving. An indirect good from the war has been the lessons we have learned on these subjects. On the extent to which we learn them and apply them will chiefly depend the future of American business. That future must be one in foreign fields, for the output of our factories is too large for our domestic markets continuously to take it all. Nor can we maintain our domestic credits under the altered conditions by sales in the domestic market alone.

Let us go to the industrial contest then as we go to the field of war, with trained men, led by trained leaders, knowing the job and stripped of all wasteful encumbrances. This done, America has little to fear. The business of the country will find the Government ready to go hand in hand with it in securing its full share of the commerce of the world.

---

THE saving effected by increasing the vacuum one-tenth of an inch of mercury will amount to approximately one-tenth of a pound of steam per kilowatt hour at full load.

# PROGRESS IN NEW EQUIPMENT

## A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

[illegible] the methods employed in their production.

[illegible] during the past three years and its de- [illegible] Wadkin & Co. [illegible], [illegible] ng" for the following description and [illegible]ustration:

The general character of the tool is [illegible] will, however, be best understood by reference to Figs. 2 to 11, which show the work in place on the machine. The blank is built up in the usual way by gluing together several layers of wood, as indicated in Figs. 2 and 3. The only change made, as compared with what is usual with hand-shaped propellers, is that the bottom lamina is left with a 4¾-in. projection at each end. In each of these projections and on the centre line a 1-in. diameter hole is drilled to a template.

The hole at the hub, which is put through at the same time, may either be bored out 1½ in. to suit the mandrel of the machine or bored out the finished size. If the latter method is adopted it is necessary to use a bush to fit the bore with a 1½-in. diameter hole for the mandrel. The propeller block is placed over the mandrel of the machine, and sits on a faceplate, and is locked by a screwed nut as shown in Figs. 2 and

[illegible] The [illegible] over a steady [illegible] locked by a hand nut.

The principle upon which the machine is based consists in forming a propeller blade by causing a roller to pass over the surface of an "original" (see Fig. 11), the path followed by this roller imparting a similar motion to the cutter arm as it passes over the work so as to cause the cutter itself to follow an exactly similar path.

Referring to Fig. 1, the bed consists of a long casting with machined ways, upon which a carriage is mounted. This carriage supports upon ways machined upon its upper face a reciprocating headstock. Upon this headstock are pivoted the cutter block and copy roller arms. These are connected at their ends remote from the cutting tool by an adjustable link. The arms are balanced by a spring, so that just sufficient weight is on the "original" as to keep the cutters in contact with the work.

The cutter block comprises 12 cutters of special shape, six cutters being on the front face of the cutter block and six on the opposite face, so that the machine will cut with equal facility in either direction. The designed speed of the cutter block is 4,200 r.p.m., and the spindle on which it is mounted runs in ball bearings. It is driven by a flat belt running over a two-step pulley, mounted on ball bearings and carried by a bracket fixed to the sliding headstock. A second flat belt running vertically downwards over guide pulleys couples the two-step pulley with the driving

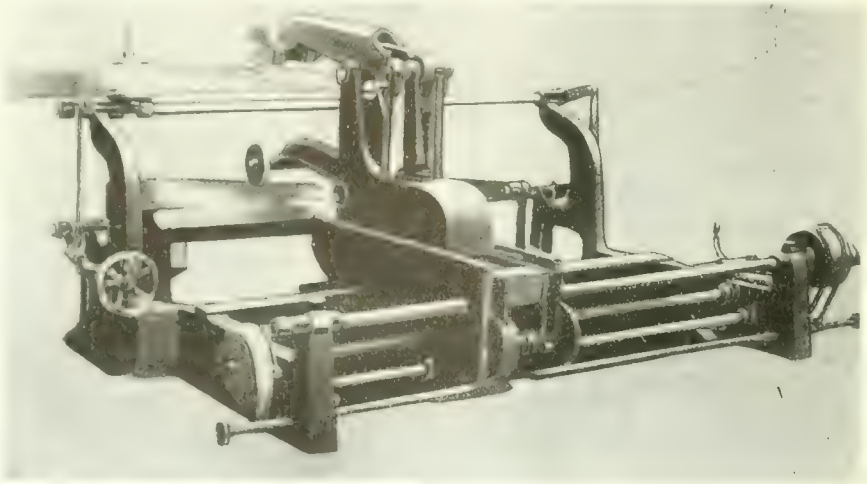


FIG. 2. AUTOMATIC SHAPING MACHINE FOR FINISHING AEROPLANE PROPELLERS

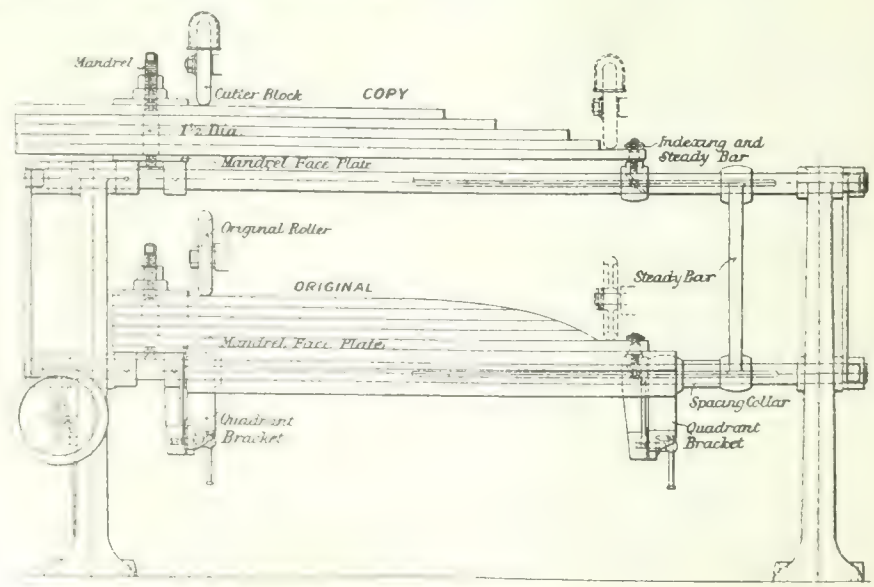

FIG. 3. FRONT ELEVATION.

pulley, which is fixed and traverses with the carriage along a splined shaft. This shaft carries at one end a pair of fast-and-loose pulleys, and also a pulley for driving by means of crossed and open belts the carriage-feed mechanism.

Steel reduction gearing contained in a gear-case connects the driven pulleys of this feed mechanism with a driving shaft for giving the reciprocating motion to the headstock on the carriage, and also for giving the longitudinal traverse to the carriage by means of a screw. Two stout horizontal turned bars, mounted in a pair of brackets, are used to carry the mandrels and faceplate for supporting the work and the "original" or copy. The method of mounting the propeller block upon the mandrel and the steady-pin at its opposite end has already been explained, and the "original" is mounted in exactly the same manner. It will be noticed that wooden guides (Figs. 6 and 7) are provided at each side of the "original" so as to provide a support for the roller on leaving the surface of the "original."

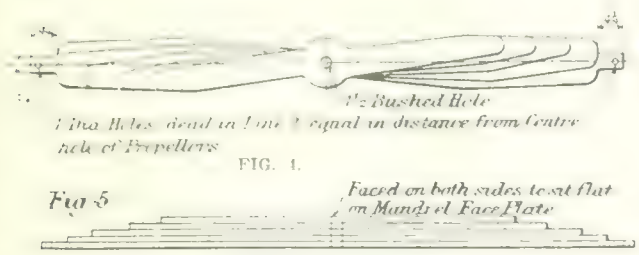

FIG. 4.

FIG. 5.

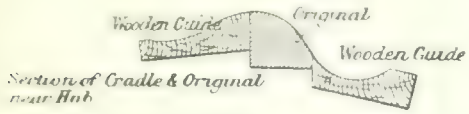

FIG. 6.

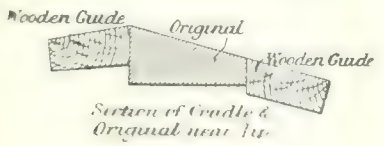

FIG. 7.

The "original" consists of a wooden block shaped on one side only, exactly as the finished blade for the face side, and a similar block for the back side. These are shown separately in Figs. 6 and 7 and Figs. 9 and 11. By adopting this method a very stiff "original" is obtained, which can be quickly made by the manufacturer in his own shop. The wooden guides are fixed to quadrant brackets mounted on the "original" supporting bar, and can be locked in any suitable position. These platforms are easy motion to the roller arm as it passes backwards and forwards over the "original."

Owing to the variable shape of the propellers a motion is provided so that the "original" and the propeller block are tilted simultaneously by means of parallel links and a worm and worm-wheel motion, operated by hand wheel (best seen in Fig. 2), in order to facilitate the passage of the "original" roller in its traverse.

It is claimed that a 10-ft. two-bladed propeller may be cut in 1¾ hours by this machine at a [illegible]

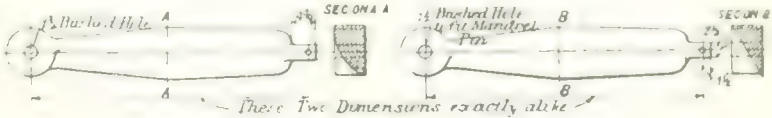

FIG. 8.

FIG. 10.

FIG. 9.

FIG.

which gives a very good finish to the work. Other rates of feed may be fitted to the machine if desired, which will enable a propeller to be shaped in 70 minutes with a slightly coarser finish. A four-bladed propeller is cut in exactly double these times. The amount of attendance required is small, and in some shops one man runs three machines, since they are entirely automatic, and merely require starting and stopping as each blade is cut, in addition to placing the work in and out of the machine.

The machine is made in two sizes, siz., to take propellers up to 12 ft. and 14 ft. diameter, both of which will take work 9½ in. through the hub and 16-in. width of blade. The actual amount of time saved depends, of course, upon the size of the propeller, but taking the various figures given the propeller makers, the average is said to be well over 10 hours on a two-bladed propeller, and is in some cases as much as 14 hours.

## SEXTUPLE AUTOMATIC BAR MACHINE

THE sextuple automatic bar machine, illustrated above, is a recent product of the New Britain Machine Co., New Britain, Conn., and, while similar in many respects to the multiple spindle chucking machine described recently in these columns, differs in that it does not index, but is designed to feed, drill, chamfer, and cut off in each position, on simple work such as rolls, sleeves, couplings, etc., this makes six-fold production possible, as compared to single spindle automatics.

As in the multiple spindle chucking machine, the spindles (six in number) are of liberal diameter, hammer-forged from chrome nickel steel, heat treated, hardened and ground and run in bronze bearings of ample proportions, ground straight inside and taper outside, thus providing means for taking up wear without disturbing the alignment of the machine. Ball thrust collars are also provided on all six spindles for taking care of the end thrust due to tool pressure, this arrangement resulting in a thirty per cent. reduction in the power required to drive the spindles.

The change gears provide six rates of spindle speeds, while a separate system of change gears is provided for effecting changes in feed by varying the speed of the cam shaft.

The spindle cylinder is heavy in design

[illegible] BAR MACHINE

am is laminated in a simi- leaf spring, which con- ine. The cam shaft is driven through a large internal gear on the inner circumference of the feed cam steel roller fixed to the frame

A quiet, smooth-running machine re- gears by the generating process and from the absence of all chains and bevel gears.

Hand control levers on each side within easy reach of the operator enable the power feed to be instantly stopped or started. These, in conjunction with a hand feed crank for testing all feed movements and tool positions are valuable features, avoiding breakage in setting up, testing, and adjusting tools.

The oil distributing system is designed to avoid as much exterior piping as possible. This is accomplished by conveying the oil through the underside of the tool slide into a chamber at the center surrounding the driving shaft bushing, from which it is tapped off at the circumference through short tubes to the individual tools. The oil pump is driven at constant speed.

The base, forming the chip pan, extends to the floor, thus dispensing with legs, and the broad foundation thus obtained, together with the stiff construction and ample weight of the machine, tends to prevent vibration and to insure smooth, accurate work. That portion of the bed directly beneath the work has a 45 degree slant toward the rear of the machine so that the chips are carried to the side as they are cut off. The chip pan is widest on the rear side, and slopes toward the rear end where there is an oil well and strainer, from which the oil is pumped and distributed to the work. This construction permits the draining off of the oil before the chips are removed and makes it possible to rake out the chip pan without stopping the machine or removing the splash apron.

Armagh, Que.—The Town Council will ... The engineers are Gouvin & ... Quebec.

## TO PROTECT WORKERS AGAINST POISONS.

SECRETARY McAdoo announces that the United States Public Health Service, of the Treasury Department, has begun the collection and dissemination of information aimed to protect the lives of workers engaged in war industries.

One of the greatest dangers to the workers in the highly developed munitions industry is from the nitro and amido compounds of benzol and toluol, one of which, trinitrotoluol, is very generally used as a powerful explosive. Workers are exposed to this substance in its manufacture and in shell loading.

### Guarding Against Poison.

It is readily absorbed through the skin and respiratory tract. Although such absorption cannot be prevented altogether, it can be made so slight that no workers, except, perhaps, those especially susceptible, will have symptoms of chronic poisoning.

The Public Health Service has published an article giving practical points in the safe handling of trinitrotoluol and dealing primarily with the shell-loading processes. The shells are loaded in two ways. The compound is either pressed into the shell by power presses while in powdered form, or is poured into them while in molten form. In the former method, used only in the case of large shells, simple measures will prevent poisoning. The article, therefore, deals principally with precautions to be taken where the latter method is used. The various stages of the process are considered in detail and many suggestions made as to how the hazard can be minimized.

It is also recommended that workrooms be constructed to secure complete segregation of each stage in the process of loading; that long, narrow, one-storey buildings be used; that a conveyer system be adopted to avoid unnecessary handling of the substance; that workers be instructed as to the danger of poisoning; that they secure as complete protection of the person as possible by overalls, caps and gloves; that they avoid all alcoholic beverages; that they take milk or milk products with their breakfast previous to starting work; that they observe the strictest personal cleanliness; that persons under 21 be kept from handling the compound, as they are especially susceptible to the poison; that men be employed for only 8 hours a day when working with trinitrotoluol; that those employed in the most hazardous parts of the work be rotated to less hazardous processes at least every two weeks; and that an efficient system of medical supervision be established.

## AUTOMOBILE DEVELOPMENTS IN ITALY

By B. L. E.

TURIN, Italy's most important automobile center, is a bustling place in these days. Unlike the motor car firms of England and France, the various Italian motor car firms have been allowed to ... on the class of work for which they were originally designed. The Italian factories have, we learn, not only a greater car output than at any period of their history, but they have increased at a greater ratio than those of other allied nations.

It is not possible to predict now far this progression will continue in the future, for the demands of the war may make it necessary to change the nature of the output of the motor car factories. Already, however, the Italian factories are reaping the benefit of the settled policy of the Government when they joined in the war, and they will continue to benefit.

It is not possible to obtain, or advisable to publish, absolutely accurate figures regarding the number of workers and the output of the Italian factories. By far the biggest concern, we are told, is Fiat, with a staff of 23,000 workpeople, compared with 5,000 in 1914. The other important factories are Lancia, Spa, Itala, Scat, and Diatto, with Bianchi, Isotta-Fraschini, and Zust at Milan, the combined staffs of which barely exceed that of the Fiat Co.

While all the factories have increased their area, that of the Fiat Co. is enormous. From 83,000 square yards in 1914, the factory buildings have grown to 600,000 square yards at the present date. At a time when much attention is being paid to the value or otherwise of specialised shop and assembly plants, it is interesting to note that Fiat is developing in the opposite direction, so that at no distant date every part of the Fiat cars, with the exception of the tires, will be built in the Fiat establishments. At the present time the whole of the forgings are made by the Fiat Co. Electrical equipment, which is generally considered an outside branch, is now an important and integral part of the factory. For a considerable time now the firm has been making all its own dynamos, starting motors, coils, etc. The same applies to radiators and lorry driving chains, which are entirely built up from the raw material by the Fiat Co. All foundry work, whether it be steel, cast iron, aluminum, or bronze, is Fiat produced. The same is true of all forgings, such as crankshafts, connecting rods, valves, etc. Further than this, the firm is making itself independent of outside control by producing a very large number of its own machine tools. Development on these lines is only possible with an immense output.

**Arthur Surveyer** and **R. DeL. French** have formed a partnership as Arthur Surveyer & Co., consulting engineers, with offices at 274 Beaver Hall Hill, Montreal. Mr. Surveyer, who is a member of the Honorary Advisory Council for Scientific and Industrial Research, has been engaged in consulting practice for many years past. Since 1911 Mr. French has been principal assistant engineer with R. S. and W. S. Lea, consulting engineers, Montreal, and at the same time served on the staff of McGill University as lecturer in civil engineering.

## WESTERN CANADA'S COAL

THE Alberta coal interests see in the present situation in Eastern Canada and United States a pretty likely looking peg on which to hang a new campaign. This particular campaign seeks to fence off the coal buyers of Western Canada for the Alberta coal fields.

There's nothing particularly new in this. As a matter of fact the Alberta fields have been lacking the stability that a good, steady market would give.

There must be a dead-line some place in Western Canada, east of which it will not pay to ship Alberta coal, and west of which it is not practicable or advisable to send the product of the Pennsylvania mines.

The publicity campaign carried on by the West this year has its point in trying to shove this coal dead-line as far East as possible

Westerners are not quick to tie up entirely to the Alberta or British Columbia supply. They don't like to store Alberta coal in large quantities, claiming it burns better and has more volatile matter when fresh from the mines. The coal men meet this with the claim that under proper conditions summer storing can be adopted.
